that the analogy with temporal re-identifications in the actual world, urged by Hintikka, lends no comfort. Of his particular semantic theory I offered no criticism, though I shall, at the end, in a modest way.

Regarding the analogy of cross-world identification with temporal re-identifications, Hintikka writes, oddly, that “Quine has signalled his qualified agreement.” What agreement? I cheerfully acknowledged that “identification of an object from moment to moment is indeed on a par with identifying an object from world to world.” How? “Both identifications are vacuous, pending further directives.” Then I went on to show how the further directives ready to hand in the one case were wanting in the other. Was this touch of irony misleading?

Apparently another one was. Hintikka quotes me thus: “This brings matters gratifyingly close to home. It is very ordinary language indeed to speak of knowing who or what something is.” Who can deny it? There is indeed the overtone, ironically intended, that ordinary language is clear. It was dispelled, I hoped, by my next sentence: “However, ordinaryity notwithstanding, I make no sense of the idiom apart from context.” No, not dispelled. Hintikka de­plores at some length my inversion of the “heuristic priorities”, my preference for “pretheoretical insights” over formal theory construction, and notes (rightly enough) that “the mistake... is more than a little strange for Quine of all people to commit.” Let me stress all flat-footedly, and not for the first time, that familiarity carries no presumption of clarity. It merely breeds contentment.

Substitution of new and unfamiliar symbols for familiar and unclear expressions is not, on the other hand, of itself a step toward clarity. On the contrary, again. I think here of Hintikka’s two styles of existential quantifier. Do these, between them, exhaust the senses in which we may ask who or what someone or something is? Or, again, why does he deny that they are ordinary quantifiers with differently restricted ranges? His paraphrase of his (15) suggests that the quantifier in (15) is indeed an ordinary quantifier ranging over what he calls visual objects.

W.V.Q.
(3) \((\exists x)(x \text{ is a sloop} . \text{ I wish that: I have } x)\) and the notional sense of the reformed vernacular sentence is symbolized as:

(4) \(\text{I wish that: (} \exists x)(x \text{ is a sloop} . \text{ I have } x)\)

(The colon is used syntactically, and only temporarily, to demarcate the complement to the operator.)

The remainder of the first few pages of Q&PA strengthens and develops this theme with respect to seeking (rewritten as “striving that: one finds . . .”), hunting (a variety of seeking), and finally, the first and foremost of the propositional attitudes, believing (which requires no rewriting in its primary use). In each case the contrast between relational and notional readings may be strikingly represented in terms of permutations of quantifier and verb.

Beautiful! Another triumph for elementary logic! (And who would begrudge a little premeditated violence for so elegant an achievement?)

But wait; now comes the transition. “However, the suggested formulations of the relational [readings] . . . all involve quantifying into a propositional-attitude idiom from outside. This is a dubious business . . .”

What a downer! Why has Quine undercut his own logical triumph with gloomy doubts? One immediately thinks of the problems of interpreting modal logic and of the awful consequence of the third degree of modal involvement, namely, the metaphysical jungle of Aristotelian essentialism. But whereas the relational readings of sentences involving necessity lead into the jungle (and good riddance, says Quine), “we are scarcely prepared to sacrifice the relational constructions” that (3) and others like it are supposed to represent. Quine does not doubt that quantification into propositional attitudes makes epistemological sense. The opening pages of Q&PA, and in particular the contrast between (3) and (4), show us just what sense it makes.
of any language that combines quantification with opacity. The purported theorem says that in a sentence, if a given position, occupied by a singular term, is not open to substitution, then that position cannot be occupied by a variable bound to an initially placed quantifier. The proof offered assumes that quantification receives its standard interpretation. But the attempted proof is fallacious. And what is more, the theorem is false.

It is very important to separate the 'logical' problems raised by the alleged theorem from any metaphysical or epistemological problems raised by the interpretation of relational constructions. The former are independent of the specific nature of any particular opacity producing phrase, whereas the latter depend on the particular opacity producing notion such as necessity or belief. Quine has advanced both sorts of arguments against quantified modal logic. These arguments had, to some degree, run together in my mind and perhaps in the minds of others as well. I intend now to run them apart.

The structure of Q&PA makes it clear that, at least at that time, Quine himself distinguished these two sorts of arguments. In Q&PA, relational readings of sentences involving propositional attitudes are not problematical; they are indispensable. The alleged theorem is the problem. This problem is ultimately resolved by retracting from the early and elegant analysis in terms of syntactical ambiguity—the representation in terms of permutation of quantifier, and verb—to the conclusion that there exists a lexical ambiguity in the propositional attitude verbs themselves. Thus, there is a relational sense of 'wishes' that which admits both substitution and quantification, and there is a notional sense which admits neither. The two senses differ in logical syntax and cannot be transformed into one another by moving quantifiers around. Indeed it is this syntactical difference which allows them both to conform to the requirements of the alleged theorem and, at the same time, to serve the work of (3) and (4). If we describe the ambiguity of sentences as being resolved by readings, and the ambiguity of lexical items as being resolved by senses, we may say that there are two readings of the ambiguous vernacular sentence “I want a sloop”, and that the two readings require different senses of the (concealed) propositional attitude verb. (Contrast this with the two readings of “Everyone is not hungry”, which merely require grammatical re-parsing and do not require one sense of ‘not’ for application to closed formulas and another for open formulas.) This form of solution again demonstrates that it is a point of logical grammar, not the intrinsic intelligibility of particular relational readings that is here at issue for Quine.

It is evident that the same technique—propounding a lexical ambiguity between notional and relational senses—could be used to skirt the alleged theorem in the case of modalities. But there Quine is convinced that the metaphysical problems of interpreting the relational sense of necessity are so great that it is not worth the effort to avoid the logical problem. I will not now argue with Quine’s metaphysics, only with his logic.

But first I should state that although I believe Quine erred, I appreciate his ingenious attempts to avoid the consequences of his alleged theorem and to point out its consequences for the theories of others. In this undertaking he has provided us with a rich field of ideas, always fascinating and sometimes puzzling, ranging from the two senses of “belief” in Q&PA through the “stubborn objects” of Word and Object to the trans-world “physical objects” of Worlds Away. It is my hope that a careful examination of the details of his semantical and logical arguments will help us to get a clearer perspective on the larger and more philosophically central issues in metaphysics and epistemology.

III

It is my intention to present what I take to be Quine’s argument for the alleged theorem in a form more explicit than any in which it appears in his writings. To this extent, I speculate. My primary source, as noted above, is “Notes on Existence and Necessity” (Notes on E&N), though I state some parts of the argument in a way more reminiscent of “Reference and Modality” (R&M) and some later papers.

Notes on E&N opens and closes with passages that make it unmistakably clear that the work aims to establish general principles of logic and semantics which limit the logical form in which a theory of modality can be cast. Thus the opening two paragraphs:

This paper concerns two points of philosophical controversy. One is the question of admission or exclusion of the modalities—necessity, possibility, and the rest—as operators attaching to statements. The other is the ontological question, “What is there?” It is my purpose here to set forth certain considerations, grounded in elementary logic and semantics, which—while not answering either question—must seriously condition any tenable answers.

The logical notions that prove crucial to these considerations are the notions of identity and quantification; and the semantical ones are the notions of designation and meaning, which are insufficiently distinguished in some of the current literature. A new semantical notion that makes its appearance here and plays a conspicuous part is that of the “purely designative occurrence” of a name. (emphasis added)

The closing paragraph states four main conclusions:

(i) A substantive word or phrase which designates an object may occur purely designatively in some contexts and not purely designatively in others.

(ii) This second type of context, though no less “correct” than the first, is not subject to the law of substitutivity of identity nor to the laws of application and existential generalization.
Moreover, no pronoun (or variable of quantification) within a context of this second type can refer back to an antecedent (or quantifier) prior to that context.

This circumstance imposes serious restrictions, commonly unheeded, upon the significant use of modal operators, as well as challenging that philosophy of mathematics which assumes as basic a theory of attributes in a sense distinct from classes.

It is conclusion (iii) which I describe as the alleged theorem. Note that (iii) is not conditioned by any metaphysical or epistemological hypotheses. The challenge, mentioned in (iv), to the theory of attributes is again an unconditional application of the alleged theorem. “Expressions of the type that specify attributes [for example, ‘the attribute of exceeding 9’] are not contexts accessible to pronouns referring to anterior quantifiers.”

My reconstruction of Quine’s argument that the failure of substitution implies the incoherence of quantification may now be stated as follows:

Step 1: A purely designative occurrence of a singular term in a formula is one in which the singular term is used solely to designate the object. [This is a definition.]

Step 2: If an occurrence of a singular term in a formula is purely designative, then the truth value of the formula depends only on what the occurrence designates not on how it designates. [From 1.]

Step 3: Variables are devices of pure reference; a bindable occurrence of a variable must be purely designative. [By standard semantics.] 14

Notation: Let \( \phi \) be a formula with a single free occurrence of ‘\( x \)’, and let \( \phi_\alpha, \phi_\beta, \phi_\gamma \) be the results of proper substitution of the singular terms \( \alpha, \beta, \gamma \) for ‘\( x \)’.

Step 4: If \( \alpha \) and \( \beta \) designate the same thing, but \( \phi_\alpha \) and \( \phi_\beta \) differ in truth value, then the indicated occurrences of \( \alpha \) in \( \phi_\alpha \) and of \( \beta \) in \( \phi_\beta \) are not purely designative. [From 2.] 15

Now assume 5.1: \( \alpha \) and \( \beta \) are co-designative singular terms, but \( \phi_\alpha \) and \( \phi_\beta \) differ in truth value, and 5.2: \( \gamma \) is a variable whose value is the object co-designated by \( \alpha \) and \( \beta \).

Step 6: Either \( \phi_\alpha \) and \( \phi_\gamma \) differ in truth value or \( \phi_\beta \) and \( \phi_\gamma \) differ in truth value. [From 5.1, since \( \phi_\alpha \) and \( \phi_\beta \) differ]

Step 7: The indicated occurrence of \( \gamma \) in \( \phi_\gamma \) is not purely designative. [From 5.2, 6, and 4.]

Step 8: It is semantically incoherent to claim that the indicated occurrence of \( \gamma \) in \( \phi_\gamma \) is bindable. [From 7 and 3.]

All but one of these steps seem to me to be innocuous. 15 That one is step 4 which, of course, does not follow from step 2. All that follows from 2 is that at least one of the two occurrences is not purely designative. When 4 is corrected in this way, 7 no longer follows.

The error of step 4 appears in later writings in a slightly different form. It is represented by a subtle shift from talk about occurrences to talk about positions. Failure of substitution does show that some occurrence of a term in that position is not purely referential. 16 From this it is concluded that the context (read ‘position’) is referentially opaque. 17 And thus that what the context expresses “is in general not a trait of the object concerned, but depends on the manner of referring to the object.” Hence, “we cannot properly quantify into a referentially opaque context.” 18 The shift from talk of irreferential occurrences to talk of irreferential positions links “some occurrence of a term in that position” to “all occurrences of terms in that position,” and so induces the fatal step 4.

It would be easy to make the mistake in step 4 if, like Quine, one tended to see all singular terms other than variables as short for natural or contrived descriptions. There would then be no evident reason, in a concrete case of substitution failure, to discriminate between the supplanted term and the supplanting term in charging irreferrality. There would be no reason to expect variability among terms in their disposition to go irreferential in a given position, with, say, the supplanted term purely referential but the supplanting term not.

On the other hand, it should be difficult to make the mistake of thinking that a variable cannot occupy a bindable position in which there is substitution failure for constant terms if, like Quine, one interpreted substitution failure as showing that neither the supplanted nor the supplanting occurrences were purely referential. For then, as Quine says, neither the pre-substitution sentence nor the post-substitution sentence is really about the referent, and hence neither sentence speaks to the meaningfulness of quantification in, which is about the referent. Far from demonstrating that quantification in is illegitimate, the diagnosis (for constant terms) of irreferential occurrence asserts the irrelevance of the test. Only if our test revealed a substitution failure in which both the supplanted and the supplanting terms had purely referential occurrences, would it show that we could not meaningfully quantify in. Given Quine’s criterion, such a test result is unlikely. But the contrapositive is enlightening. It tells us that if quantification into a context:

\[ \ldots x \ldots \]

is legitimate, then

\[ (x)(y)((x = y) \supset (\ldots x \ldots \equiv \ldots y \ldots )) \]

is true.
In a discussion of this matter in Dubronvnik, Yugoslavia in Spring 1979, a thoughtful exponent of Quine's views (who immediately saw the fallacy in the argument as reconstructed above) put it this way: There are two kinds of variability involved. First, a given singular term can have both purely designative and non-purely designative occurrences, and second, a given position in a formula can be filled at one time by a purely designative occurrence of a term (for example, a variable) and then by a non-purely designative occurrence (for example, a definite description). In 1943, Quine saw the first kind of variability but not the second. 19

I commented that the (tacit) assumption that there is no variability in the position was in accord with the great classical tradition of Fregean semantics. On Frege's analysis it is the context (that is, the position) that determines the semantics of whatever singular term occupies the position. 20

From Frege’s point of view, step 4 is correct. Alonzo Church assumes this point of view in his formalization of Frege’s logic of sense and denotation. Church’s formalization conforms to Quine’s proscription. 21

Church, in his review of Notes on E&N, 22 was the first to call attention to the relationship of Quine’s paper to Frege’s ‘Über Sinn und Bedeutung.’ 23 As will become more apparent in subsequent remarks, I see Quine, like Church, as being drawn down the same path as Frege, except that Quine travels light, without the baggage of intensional entities that is widely viewed as the hallmark of Frege’s way.

In the first footnote to R&M, Quine himself identifies his notions of purely referential and non-purely referential occurrences with what he calls Frege’s “direct (gerade) and oblique (ungerade) occurrences”. Interestingly, Quine, typically unwilling to accept Frege’s notion of indirect (oblique) denotation (ungerade Bedeutung) with its ontological commitment to senses (Sinne) as entities, here invents and attributes to Frege the denatured idea of an indirect (oblique) occurrence—definable in Fregean terms, I suppose, as one which would have indirect denotation if there were such a thing. 24

So far I have not shown that the alleged theorem is false, only that my reconstruction of a proof for it is fallacious. It happens, however, that the very notions Quine uses in Q&PA to resolve the doubts caused by the alleged theorem can be used to build a counter-instance to it. This gave added poignancy to my puzzlement as to what motivated the transition in Q&PA. If the developments following the transition were correct, there was no need for them.
the basis of a technicality, not by a substantive proof of innocence. In 1968 I
coly described the shifty operator as "An intriguing suggestion for notational
efficiency at no loss (or gain) to Quine's theory." But I meant more than
that. I meant it to be recognized that if we interpret the symbolization lesson
of Q&PA as containing shifty operators, then we both legitimize the syntax
(from Quine's point of view) and we retain exactly our naive understanding of
such formulas as (3) and (4), the naive understanding that originally gave the
symbolization lesson its edifying punch.

At this point I must confess to a residual unease and to a sympathy for the
now discredited but well-intentioned alleged theorem. Does re-ambiguation
show that the combination of quantification and opacity is coherent? Re-ambi-
guation is a notational unification of what is conceptually disparate (another of
those dubious but indispensable notions). It can be elegant fun to try to do this
in a way that makes the stitching almost invisible, and it must be granted that
what started as a task for invisible mending may end up in displaying new
conceptual affinities, but we should not let delight in the handiwork blind us to
the underlying question of conceptual coherence. It is possible that our original
reading was incoherent (in the dubious but indispensable sense) and it is just
dumb luck that, as it turns out, we can get away with it. On the other hand,
we have not foreclosed the possibility of there being another conceptualization
of the semantics of a notationally unified treatment of the propositional attitudes
which, unlike the logician's trick, is coherent. I think there must be such a
conceptualization. Our naive understanding is too natural, and the logician's
trick is too unnatural, for it to be just dumb luck.

At the time of my 1968 footnote I did not intend the logician's trick as
proof that there was no logical difficulty with quantifying in because I did not
then clearly recognize that it was a purported logical difficulty that drove
Q&PA into the transition. But I recognize it now. And the trick is proof that
the alleged theorem is no theorem, at least on the hypothesis that there is no
further logical disability that affects all relational senses (but see Part D below).
The logician's trick shows that quantification into a single undifferentiated no-
tation for an opacity producing lexical item is just as secure as quantification
in the form of the sentence. "Orcutt is a spy" expresses a singular propo-
sional form. Of the sentence. "Orcutt is a spy" expresses a singular propo-
sion that makes the unified object at one with the unified objects of the notional
senses. Quine's exposition of these matters tends to begin by invoking inten-
tional entities (for their intuitive value in marking dramatic contrasts), and to
conclude with a retreat—or is it an advance—to linguistic entities (for their
certain structure and secure ontology). So the task, if we are to follow his
trail, is first, unification in the theory of intensional objects, and then, unifica-
tion in the theory of linguistic objects. I believe both tasks can be accom-
plished, though both require deviations from dominant modes of thought. Let
us begin with the intensional.

I have suggested that the alleged theorem, and its consequences in terms of
disambiguation and the disquietingly smug re-ambiguation, flow from a Fre-
gean outlook on problems of opacity and the nature of intensional entities. A
quite distinct point of view was championed by Russell. Russell thought that all sentences stand for propositions. He distinguished
two sorts of propositions. There are propositions (call them singular) that
attribute properties directly to an individual, by having the individual itself oc-
cupy the subject place in the proposition. And there are propositions (call them
general) in which individuals are only represented under descriptions, that is,
the subject place in the proposition is occupied by a complex of properties
which was said, in turn, to denote the individual. Quantified forms were also
regarded as general. In this way the form of the proposition was thought to
mirror the form of the sentence. "The man in the brown hat is a spy" expresses a singular propo-
sition with a simple subject, Orcutt himself, and the property of being a spy
as attribute. "The man in the brown hat is a spy" expresses a general propo-
sition with a complex subject which contains the property of being a man and
of wearing a hat, etc. If we were willing to accept the hypothesis that the
meaning of a grammatically simple name is just the individual named, we
could say that the subject of the proposition is the meaning of the grammatical
subject of the sentence. But we need not accept that hypothesis in general.
Russell didn't.
It is my thesis that the fundamental difference between Russell and Frege emerges in their views about singular propositions.\textsuperscript{32} As I have noted, these entities are fundamental to Russell's intensional ontology. Frege was bewildered by the idea that a proposition, the objective content of thought, something capable of being apprehended by the mind, might contain a stark individual not represented by some mode of presentation.

In late 1904 Frege set out, in correspondence with Russell, to answer Russell's scepticism about the thesis that sentences (or perhaps propositions) stand for truth values in the way that complex definite descriptions stand for objects. (Russell had written, "For me there is nothing identical about two propositions that are both true or both false.") In a lengthy expository of his theory, Frege remarks in passing:

Truth is not a component part of a thought, just as Mont Blanc with its snowfields is not itself a component part of the thought that Mont Blanc is more than 4,000 meters high.

Russell responds:

I believe that in spite of all its snowfields Mont Blanc itself is a component part of what is actually asserted in the proposition 'Mont Blanc is more than 4000 metres high'. We do not assert the thought, for this is a private psychological matter: we assert the object of the thought, and this is, to my mind, a certain complex (an objective proposition, one might say) in which Mont Blanc is itself a component part. . . . In the case of a simple proper name like 'Socrates', I cannot distinguish between sense and Bedeutung; I see only the idea, which is psychological, and the object.\textsuperscript{33}

This is not the place to enter into an exact analysis of Frege's and Russell's theories of intensional entities, nor is it the place to defend Russell's theory or his understanding of Frege's theory. Let me just assert that despite Frege's incredulity,\textsuperscript{34} current theories of reference suggest that Russell's ideas provide the more natural interpretation of what is expressed by everyday utterances involving proper names, indexicals, and demonstratives. And, most importantly for our purposes, they provide for the first step in unification, unifying subject and predicate. We can unite the property being more than 4,000 meters high with Mont Blanc itself (with all its snowfields) to form a single object of thought.

Once the objects of propositional attitude constructions contain individuals as components, quantification breezes in.

It seems quite clear that for Russell, the existence of singular propositions did not depend on there being sentences which expressed them. He increasingly narrowed the range of what he called logically proper names (names whose meaning is just the individual named) and ultimately came to regard most grammatically simple names as disguised or abbreviated complex descriptions. In this he followed Frege. But in Russell's ontology the singular propositions, even if unexpressed, retain a kind of pre-eminence. This is because his analysis of even those general propositions expressed by closed quantified sentences depends on his notion of a propositional function, which is nothing more than a function from individuals to singular propositions containing them.

As I see Russell's intensional semantics, it recapitulates extensional semantics by analyzing the intension of quantified sentences in terms of the intension of open sentences under assignments of values to free variables. An open formula expresses a singular proposition for every assignment of values to its free variables. If we hypostatize the way in which a given open formula associates singular propositions with values of its variable, we obtain a propositional function. The closure of an open formula expresses the attribution of a second order property to the propositional function associated with the open formula. Thus singular and general propositions are related as open to closed formulas and perhaps, given Russell's remarks about the simple proper name "Socrates", as instances to generalizations. This is the second step in unification, uniting the singular propositions with the general.

If we adopt this Russellian point of view, we can smooth the awkwardness of the logician's trick. Phrases like "believes that" and "wishes that" are thought of as standing for relations between the individuals designated by their subject and the propositions expressed by their sentential complements. Perhaps it would be more perspicuous to recut these phrases so as to capture more graphically the idea that they relate two entities, a person and a proposition. We regard "that" as an opacity-producing sentential operator. Applied to an open or closed sentence, it yields, under an assignment of values to variables, a name of the proposition expressed, under that assignment, by the sentence. We regard "wishes" as a relation between persons and arbitrary propositions. Thus (3) becomes:

(5) \((\exists x) (x \text{ is a sloop} \cdot \text{Wishes (I, That } [I \text{ have } x])\)

and (4) becomes:

(6) \text{Wishes (I, That } [\exists x] (x \text{ is a sloop} \cdot \text{I have } x)]\)

The two steps in unification are seen in the notation. "That", operating on open sentences, yields a name of a singular proposition, thus unifying subject and predicate; the use of the relational "Wishes", with a place for arbitrary proposition names, unifies singular and general propositions.

VIII

Quine's familiar method for moving from intensional objects to linguistic ones amounts to replacing the "That" operator with quotation marks. (6) is transformed into:

Wishes (I, "(\exists x) (x \text{ is a sloop} \cdot \text{I have } x)"")
which is read something like:

\[ \forall x (x \text{ is a sloop } \land \text{I have } x) \]

In Q&PA and again in "Intensions Revisited" Quine raises, and replies to, various objections to this transformation. Those objections are not at issue here. But Quine himself would object to the transformation of (5) into:

\[ \forall x (x \text{ is a sloop } \land \text{Wishes (I, } \forall x \text{ I have } x) \]

insisting that the quantifier cannot bind the final occurrence of "x" through the opacity of quotation. That sounds like the last stand of the alleged theorem.

Let's try to work around it.

There is a natural move to make. We resort, as before, to the familiar notion from extensional semantics: an assignment of values to variables. We replace

\[ \text{Wishes (I, } \forall x \text{ I have } x) \]

which was read:

\[ \text{I wish-true } ' \forall x \text{ I have } x' \]

with

\[ \text{Wishes (I, } ' \forall x \text{ I have } x', y) \]

(\text{with quantifiable } 'y') which is read:

\[ \text{I wish-true } ' \forall x \text{ I have } x', \text{ with respect to } y \text{ as value of } 'x' \]

This, in effect, is exactly where Quine comes out in Q&PA. He would read (7) as:

\[ \text{I wish } ' \forall x \text{ I have } x' \text{ to be satisfied by } y \]

in which the words "wish to be satisfied by" are viewed as an irreducibly triadic predicate. (I have reason for preferring the reading (8) as will become clear below.) The last stand of the alleged theorem has forced us back to the syntax of a relational sense, segregating subject and predicate. Drat!

Can we again do the logician's trick and stitch together the dyadic "wishes-true" with the irreducibly triadic "wishes to be satisfied by"? Here, Quine has pointed the way in the very first example in Notes on E&N. He there demonstrates how two occurrences of an expression, one purely designative and one within quotes, can be consolidated into a single occurrence. He (implicitly) urges these efficiencies upon us with the encouraging remark that "it is easy, in fact, to translate".

Giorgione was called "Giorgione" because of his size into

Giorgione was so called because of his size.

We will follow Quine's recommendation and interpret our new quotation device using his method of consolidation.

We introduce the new quotation device: arc quotes,\( \text{ } ^{\text{arc quotes}} \), in a way that results in the expressions:

\[ ^{\text{arc quotes}} \text{I have } x \]
\[ ^{\text{arc quotes}} \text{x has } y \]
\[ ^{\text{arc quotes}} (\exists x) \text{ I have } x \]

being taken to abbreviate, respectively:

"I have x" with respect to x as value of "x"
"x has y" with respect to x as value of "x", y as value of "y"
"(\exists x) I have x"\[ ^{\text{arc quotes}} \]

What we have achieved is not quite shifty quotation. An open formula enclosed in arc quotes is not regarded as a well-formed part of the larger expression within which it stands. Instead it is regarded as a syncategorematic expression which in combination with an operator phrase produces a shifty operator. Using arc quotes we can now rewrite an instance of the Quine-like (7) as:

\[ \text{Wishes (I, } ^{\text{arc quotes}} \text{ I have } x) \]

with quantifiable 'x'. Quine would surely no longer object to the transformation of (8) into:

\[ (\exists x) (x \text{ is a sloop } \land \text{Wishes (I, } ^{\text{arc quotes}} \text{ I have } x)) \]

A dream realized: quantifying into quotes!

Again we have a logician's trick, a reorganization of notations to smooth the surface, but with no reorganization of the subject matter. We have been syntactically creative but ontologically conservative. We are left with a shifting relation between surface and subject. Can we replace the logician's trick with a coherent interpretation of our newly smoothed notation?

IX

The first step amounts to reparsing and slightly rephrasing (8) to bring it into the form:

\[ \text{Wishes (I, } ^{\text{arc quotes}} \text{ I have } x, y) \]

(\text{with quantifiable } 'y') which is read:

\[ \text{I wish-true } ' \forall x \text{ I have } x', \text{ with respect to } y \text{ as value of } 'x' \]

This, in effect, is exactly where Quine comes out in Q&PA. He would read (7) as:

\[ \text{I wish } ' \forall x \text{ I have } x' \text{ to be satisfied by } y \]

in which

\[ (\forall x \text{ I have } x) \text{ under the assignment: } y \text{ to } 'x') \]

or, for short:

\[ (\forall x \text{ I have } x) \text{ under } y \text{ to } 'x') \]

is brought together as a single well-formed unit. We also reinterpret arc quotes accordingly. The genius of grammar has brought us to the discovery of a new kind of sentence, the valuated formula (or, more generally, the valuated well formed expression). A valuated formula is an open formula under an assignment of values to its free variables.

It is clear that valuated formulas are a unity of individual and predicate. Furthermore, they are naturally thought of as a kind of sentence (i.e. closed formula). Open formulas cannot do the heavy truth-bearing work of sentences. They cannot even do the light sentential work of proclaiming propositions. They are incomplete, a way-station on the road to sentences and a mere artifact of one way (admittedly, a now traditional way) of doing syntax. There are two parallel ways of completing them: closure (the syntactic way) and valuation
an expression f, the result of surrounding f with arcs is a singular term whose
piece of a shifty operator, but as a proper, opacity producing operator. Given
become ideography.

Variables must not allow their idiosyncratic graphics to
turn out to be deviant.

The deviance we are talking about here is no minor peccadillo. It goes to
one of our central issues: that all bindable occurrences of variables are purely
referential. If (B) fails, (and "=" is not 'funny'), at least one of v1, v2 has a
non-purely referential occurrence. This is incoherent. Variables serve only to
mark places for distant quantifiers to control and to serve as a channel for the
placement of values. We need no variables. We could permit gaping formulas
(as Frege would have had it) and use wiring diagrams to link the quantifier to
its gaps and to channel in values. 39

Variables are simply a way of giving the distant quantifiers wireless remote
control over the gaps. Variables must not allow their idiosyncratic graphics to
become ideography.

Arc-quotation is now seen not as a notational trick, a contextually defined
piece of a shifty operator, but as a proper, opacity producing operator. Given
an expression Γ, the result of surrounding Γ with arcs is a singular term whose
free variables are the free variables of Γ and whose value, for any assignment
f of values to its free variables, is the valuation of Γ under f. 40

Quine saw how Frege's intensional ontology (though not so described) ex-
plained opacity and rejected quantification. He also showed us how the familiar
ontology of linguistic expressions can do the same. I have aimed to describe
modifications to the two ontologies which allow them to accept (and even to explain) quantification while leaving intact the prior explanation of opacity.

Each modification involves two steps of unification: first, the unification of
individual and property (or predicate) by enlisting, or creating, a new kind of
d Entity containing individuals, and second, the assimilation of the new entities
to the old. The success of my project—to achieve conceptual coherence—de-
deps on the degree to which each step seems natural.

It will not have escaped notice that valued sentences are virtually the
singular propositions they express. They give us structure. They give us indi-
viduals. They bear truth (with respect to their language). 41

I now propose to downshift from my vivid intensionalist talk to dry linguis-
tic formulations involving valued sentences. For most of the remainder I will
stay in low gear, not only to preach to the unconverted but to manifest how
much can be accomplished with one foot on the ground. Where it is worth a
reminder that the class of sentences includes both the closed and the valued,
I shall refer to them as Sentences. Note this relativity: what Sentences there are
depends on what values the variables can take. For the most part I ignore this
relativity, assuming they can take all and only what there is. 42

The method of Sentences, as I shall call it, amounts to interpreting inten-
sional operators as if they were predicates of Sentences and interpreting the
sentence within the scope of the operator as if it were contained in arc quotes.
occupation by variables and descriptions in addition to their traditional occupants. It is a loosening of grammatical constraints. Nominalization would certainly increase expressibility, but it carries several hazards.

To the degree to which we regard our semantical methods as model-making (i.e., as a way of analyzing the notion of logical consequence for the object language) rather than as reality-describing (i.e., as analyzing the intended interpretation), fine-tuning the object language to bring it into conformity with our model may end up institutionalizing an artifact of the model that corresponds to no aspect of reality. I often think that my Platonizing model-making is artificial, but I see nothing objectionable in being realistic about the artifacts qua artifacts. We model-makers love our artifacts. Models have their own reality, and the more we acknowledge that, the less likely we are to confuse the reality of the model with the reality it models. Model-making, by helping to articulate structure, can help to make it more acceptable that there is a reality behind questioned linguistic forms. (For example, that there is relational belief or even that there are singular propositions.) But one can accept the linguistic forms and the logic induced by the model, without thinking that there must be 'hidden' aspects of the reality that correspond to unexpressed structural features of the model. In particular, the very ontology of the model, whether propositions, possible worlds, or sentences, need not mirror any aspect of the reality expressed in traditional formulations of modal logic or of the logic of propositional attitudes. So here is the first hazard of nominalization. With more that we can say, we may say too much.

Where the entities interpreted as values mirror the syntactical structure of the expressions, as in the case of our $sentences, a further hazard attends nominalization. The change in syntax produces a change in the entities themselves. This becomes clear in the case of iteration. Tarski has taught us what profound consequences attend the shift of syntax which transforms the innocuous sentential operator "it is true that" into a predicate of sentences. Montague has shown the same for the sentential operator "it is necessary that", and, with Kaplan, for a version of the sentential operator "K knows that". Any reform of syntax from sentential operator to predicate of sentences must be constrained by what we may think of as Montague's Threat: that if iteration of the operator is reformed in the natural unramified way, reflexive reference will strike.

I am not advocating that we invariably avoid the shift to predicate/name form. The operator form of truth is a bore, and we may wish to set the interesting and important problem of analyzing such apparently nominalized idioms as "She says that whatever you say is false". But our task was to find semantical methods to interpret a given, putatively puzzling, syntactical form: quantification into opacity. I want to solve that problem before going on to the 'more interesting' problem. We certainly don't need to construct a formalism just to fully articulate the structure of the new entities we have introduced; the metalanguage already does that adequately. Opacity is tough enough to deal with, even when the machinery stays behind the curtain.

XII

Here is a case of nominalization that throws light on the method of $sentences. Consider the possibility of incorporating the quotes that usually accompany the predicate "says" of direct discourse into an operator Says-quote, and thus transforming:

Ralph says "Ortcutt is no spy"

into:

Ralph Says-quote Ortcutt is no spy

Here we have a backwards syntactical reform, from predicate to operator form, with no reform in interpretation. There is, of course, a loss in explicitness and expressibility. Most importantly, for our purposes, there is the opportunity, indeed the temptation, to create nonsense by quantifying in. This is the temptation that Quine has inveighed against. It is correct that the method of $sentences never resists quantification in strictly on the grounds of ungrammaticality or 'nonsense'. But the model-theoretic intelligibility of:

(∃x) Ralph Says-quote x is a spy

doesn't require that any such sentence be true. Here is our fallback position. Says-quote is true of no valuated $sentences. We take the hard line. Intelligible, yes; true, never!

Nonsense vs. falsehood is often a close call. The method of $sentences opts for falsehood. What should we say about the standard direct discourse formulation:

(∃x) Ralph says "x is a spy"

We should say that the second occurrence of "x" is not bound to the initial quantifier, the initial quantifier is therefore vacuous, and unless Ralph is in a logic class the sentence is almost surely false. So the standard formulation also opts for false.

Truth or falsity in the standard formulation depends on what sentences, including open sentences, are in the extension of the predicate "says". Truth or falsity in the operator formulation depends on what $sentences, including valuated $sentences, are in the extension of the operator Says-quote. We have not included open sentences among the non-valuated $sentences, but we could have by using a different style of variable for quantifying into arc-quotations. So we can imagine that the $sentences include all the sentences and more. If we interpret Says-quote as having the same extension as "says", we have denominalized the syntax with no shift in interpretation. No shift in interpretation implies no valuated $sentences in the extension of the operator.
operator. This is what I call taking the hard line. In the case of \textit{Says-quote} it seems reasonable, since it is reasonable to think that we cannot say (in the direct discourse sense) valuated Sentences.\textsuperscript{51} In the case of operators not arising from denominalization, it may be less reasonable to take the hard line. But there is nothing in the method of Sentences to rule it out.

Having brought direct discourse into the operator form, \textit{Says-quote}, we may compare it with the indirect discourse operator, \textit{Says-that}, which arose in this form. I think it reasonable to count as true some quantifications into \textit{Says-that}. Thus, I take no hard line on indirect discourse. Still one would expect the extension of \textit{Says-that} to be dependent on the extension of \textit{Says-quote}, exactly how, depends in part on the resolution of the problem of \textit{exportation}\textsuperscript{52} and in part on how literal indirect discourse is required to be.\textsuperscript{53} One expects these two operators to differ independently of the hard line.

### XIII

The method of Sentences provides generally for quantification into opaque contexts but says nothing specific about which Sentences are in the extension of any particular opacity producing operator. That is a matter for the interpretation of the particular operator.

The method of Sentences imposes no 'closure' conditions of any kind on the extension of an operator, not even that if \((\exists x)(x \text{ is a spy})\) is in the extension, then so must \((\exists y)(y \text{ is a spy})\). Closure conditions would likely make it impossible to represent direct discourse as an operator, since even the simplest equivalence transformations may fail.\textsuperscript{54} Closure conditions have also been thought to be a burden on the attempt to represent certain epistemic notions in operator form, since we may lack the acumen to close our beliefs.\textsuperscript{55} I think there should be no closure conditions for arbitrary intensional (i.e., opacity producing) operators, although some intensional operators, like the modal operators, may have closure conditions of their own.

Consider the language formed by adding intensional operators to the language of first order logic. We can construct models for this language by adjoining to a model \(M\) for first order logic an appropriate extension for each operator \(O\). If the operator has no special laws of its own, any set of Sentences of \(M\) (i.e., Sentences whose 'objects' are drawn from the domain of \(M\)) is appropriate. An assignment \(f\) satisfies \("O\Gamma"\) in a model, if and only if the valuation of \(\Gamma\) by \(f\) is a member of the extension of \(O\) in the model. If no valuated Sentences are in the extension of \(O\) in a particular model, then no quantifications in will be true in that model.

Let us call the logic of this language \textit{first order intensional logic}. In the absence of closure conditions, we would expect an intensional operator to behave as if it were no more than a new non-logical non-truth-functional sentential connective. (Which is what it is.)\textsuperscript{56} We would still expect the basic laws of first order extensional logic to hold (but without any 'anomalous adjuncts' such as primitive rules permitting instantation to terms other than variables). If we assume no closure conditions, these laws wouldn’t hold \textit{within} opaque contexts, but then application of the basic laws of logic to subformulas has always been, at best, a derived rule whose derivation depended on the laws governing the possible contexts of subformulas. Both quantifier and identity laws would, of course, \textit{reach into} the opaque contexts.

You can see where I am headed. I conclude that there is a general logic for the addition of opacity producing operators to first order logic, and it turns out to be: first order logic. This, I think, was the viewpoint of Barcan and Marcus when they invented axiomatic quantified modal logic. They aimed just to add the modal operators to good old first order logic, along with some laws specific to modality.\textsuperscript{57} There are subtleties in the way in which good old first order logic is to be formulated, but that doesn’t vitiate the point (if I am correct) that the logic should be traditional.\textsuperscript{58}

The situation, it seems to me, is analogous to that of quantification theory. If the rules of monadic quantification theory are properly formulated, no changes are required for full quantification theory. All that is required is an enrichment of the language. The logic, in this sense, remains the same. This does not prevent the metalogical situation from being quite different. The enriched language requires an enriched semantics, and yields new and changed metalogical results. The enriched language of first order intensional logic also requires an enriched semantics, and will certainly affect metalogical results (for example, derived rules involving definite descriptions). Thus, my thesis: first order intensional language is an enrichment of first order extensional language, but first order intensional logic is first order extensional logic.

### Part C: ESSENTIALISM

In 1953, in “Three Grades of Modal Involvement”,\textsuperscript{59} a new theme appears in Quine’s writing. He appears to retract the alleged theorem, the \textit{logical} problem. He remarks that quantification into modal contexts “is not prima facie absurd if we accept some interference in the contextual definition of singular terms. The effect of this interference is that constant singular terms cannot be manipulated with the customary freedom, even when their objects exist.”\textsuperscript{60} A new charge is leveled. “There is yet a further consequence, and a particularly strik-
ing one: Aristotelian essentialism." Those who would quantify into modal contexts must be prepared to adopt an invidious attitude toward certain ways of specifying an individual, counting some attributes of a thing as essential, and others accidental. The ground has shifted from the logical legitimacy of quantifying into opaque contexts to its philosophical consequences.

What truth is there in the charge that essentialism is a consequence of quantified modal logic?

To apply our methods to quantified modal logic we must provide an interpretation for the necessity operator. This amounts to finding a plausible classification of the Sentences into those which are necessary and those which are not. As noted above we could view all modal operators as being false of any valued Sentence. (We would lose the usual interdefinability of "[ " and " " when either governs an open sentence.) It would be a hard line. It wouldn’t be plausible. So let us proceed.

Let me make two simplifying assumptions. First that our quantified modal language is, as is usual, the language of first order logic with identity and descriptions and with the addition of the necessity operator "[ ". Second, that there are no iterations of necessity. Hence, that which occurs in the scope of "[ " is a purely first order formula without occurrences of "[ ". This is an unusual assumption made to avoid technical complications; iteration has not been the focus of Quine’s concerns.61 Given these two assumptions, we can take the problem to be to classify the Sentences of the language of first order logic.

There is a simple and natural way to do this: classify by logical truth. A Sentence is logically true if it is true in every model. The valuation of \( \Gamma \) under \( f \) is logically true, if \( f \) satisfies \( \Gamma \) in every model. There is a technical detail here I do not wish to scant. In the case of valued formulas, logical truth requires truth even in domains which do not contain the values assigned to free variables. Assigning me to ‘\( x \)’ yields a valuation of:

\[
[y] \ y \text{ is unmarried } \supset x \text{ is unmarried}
\]

which is not true in the domain of bachelors.62 So formulas like:

\[
[y] \ F y \supset F x
\]

whose universal closures are logically true may have valuations that are not logically true. In fact, no valuation of this formula will be logically true. This calls for some adjustment in our usual semantical ways, but nothing difficult.

\[
(\exists y)(y = x) \supset [y] F y \supset F x
\]

\[
(F x \supset F y)
\]

are all logically true under all assignments.

\[
(F x \supset F y)
\]

\[
(x = y)
\]

are logically true under just those assignments that assign the same value to ‘\( x \)’ and ‘\( y \)’.

For the model-wary we can express logical truth for valued formulas in terms of first order provability. We can also thereby gain some insights into the notion. Let \( \phi \) be a formula containing the distinct free variables \( v_1, \ldots, v_n \), and let \( f \) be an assignment of values to these variables. We can capture the valuation of \( \phi \) under \( f \) in different domains by relativizing all variable binding operators in \( \phi \) to a new monadic predicate \( \pi \) not already occurring in \( \phi \). For the familiar operators of first order logic, the quantifiers and the descriptions operator, this is done in familiar ways.63 Let the result be \( \phi^\pi \).

One way in which logic is not invidious is in the fungability of individuals. Thus if the valuation of \( \phi \) by \( f \) is logically true, any valuation of \( \phi \) by an isomorphic assignment \( g \) (which maintains the same relative identities and diversities among the values of \( v_1, \ldots, v_n \)) will be logically true also. We can capture the isomorphism class by means of a conjunction of identity and non-identity formulas for the variables. Let \( f_i \) be the conjunction (in some fixed order) which contains, for every pair \( i, j \) such that \( f(v_i) = f(v_j) \), the conjunct \( (v_i = v_j) \), and which contains for every \( i, j \) such that \( f(v_i) \neq f(v_j) \), the conjunct \( (v_i \neq v_j) \). Now form the universal closure of the conditional with \( f_i \) as antecedent and \( \phi^\pi \) as consequent. If we wish to exclude the empty domain, we can add \( (\exists x) \pi x \) to the antecedent.64 The result, a closed sentence, will be a logical truth in the ordinary sense, if and only if the valuation of \( \phi \) by \( f \) is true in every model.

Let’s try it. The valuation of the formula:

\[
(\exists z)(z = x \equiv z \neq y)
\]

by any assignment \( f \) such that

\[
(\exists z)(z \equiv x \neq y)
\]

has its corresponding closure:

\[
(x)(y)[(x \neq y) \supset (\exists z)Fx \supset (\exists z)(\Gamma z . (z = x \equiv z \neq y))]
\]

which is not a logical truth. Hence, no valuation of (9) by an assignment satisfying (10) will be a logical truth. Intuitively, any valuation of (9) by such an assignment \( f \), will be false in every model in which neither \( f(‘x’) \) nor \( f(‘y’) \) is an element of the domain. In that case every element of the domain will be different from \( f(‘y’) \), but none will be identical with \( f(‘x’) \).

We have characterized a class of Sentences, the class of logical truths. By the method of Sentences, we can interpret "[ " as true of exactly the members of this class. We might call this weak form of necessity logical necessity.

Quine should be relatively happy with this interpretation of necessity. He was relatively happy to call the logically true closed sentences necessary, he just didn’t see how to extend the notion of logical truth to valued formulas. So far, so good. Now, where’s the essentialism?
XV

Curiously enough, essentialism is to be found in our notion of logical necessity. Not the Invidious Aristotelian kind (you will recall the fungibility of individuals), but the Benign Quinean kind.

Note first that the acceptance of singular properties, i.e. those which have an individual as a component, follows unto the acceptance of singular propositions as two follows unto one. In a similar way the acceptance of valuated predicates follows on the acceptance of valuated formulas. For any individual \( a \), we have the singular property of being \( a \) which uniquely characterizes it, and we even have the valuated predicate:

\[
(\langle x = y \rangle \text{ under the assignment: } a \to \langle y \rangle).^{65}
\]

According to our theory of logical necessity, such uniquely characterizing properties are essential to their bearers. Thus they confirm the presence of essentialism in our system.

It is Marcus’s law\(^{67}\) for modal logic:

\[
(x)(y)((x = y) \supset \Box (x = y))
\]

(a validity of the logic of logical necessity) that demands the presence of this form of essentialism. Benign Quinean Essentialism is Quinean because of Quine’s unswerving insistence on Marcus’s law (which is said, in “Reply to Professor Marcus”, to follow from “\( \Box (x = y) \)” by ‘substitutivity’).\(^{68}\) He admonishes us that even if we were to ignore his strictures against quantifying into positions that resist substitutivity of identity for descriptions, “this does not mean violating substitutivity of identity for variables, which would simply be a wanton misuse of the identity sign.”

Benign Quinean Essentialism is benign because it makes a specification of an individual essential only if it is logically true of that individual. It is not that benign essentialism fails to discriminate among the attributes of a thing. Every modal logic will discriminate between the attribute of self-identity and the attribute of self-identity while \( P \) (\( P \) being any contingent truth). But discrimination in favor of logical truth hardly seems invidious. You can’t be harmed by logical truth.\(^{69}\)

XVI

Quine seems not to have noticed our modest logical necessity. He may have thought that logical truth couldn’t be extended to valuated formulas directly; that it was only by way of a closed surrogate that a valuated formula could be counted logically true. The use of surrogates is a general method for the interpretation of quantification into opaque contexts. It was my method in “Quantifying In”.

The simplest way of forming a surrogate, though by no means the only way, is to associate with each value of the variables (or as many as possible) a proxy name (i.e., a closed singular term), and then to substitute for each free occurrence of a variable in the open formula the proxy name of its value. Because of opacity (i.e., the fact that different names of the individual will result in different answers to questions of logical truth for the surrogate), we must discriminate among the names of a thing and cannot indiscriminately rely on any name to serve as proxy. Thus rears essentialism of the invidious kind. Something like the intuitive idea of a tag (Marcus)\(^{70}\) or a rigid designator (Kripke)\(^{71}\) may guide our choice of proxy names. But however we choose, the resulting proxy name could hardly fail to appear essential, since if \( \alpha \) is any name, the truth of the sentence

\[
(x)(x = \alpha) \supset \Box (x = \alpha)
\]

which seems to express the fact that \( \alpha \) is an essential name, reduces to the truth of:

\[
\Box (x = \alpha)
\]

under an assignment to ‘\( x \)’ of the individual for which \( \alpha \) is name. And if \( \alpha \) is a proxy name, the truth of this formula under that assignment is defined by the truth of:

\[
\Box (\alpha = \alpha).
\]

Another way to form a surrogate is to associate with each value of the variables (or as many as possible) a proxy predicate, possibly compound, expressing a condition which specifies the individual, and then to relativize each free variable in the open formula to the predicate which is proxy for its value. There are actually two ways of doing this, with universal and with existential quantifiers, but because the existential form would lead to the obviously unacceptable result that no valuated formulas are logically true, it is natural to choose the universal form. If “\( Gx \)” were the open formula valuated by the assignment of an individual \( a \) to ‘\( x \)’, and “\( F \)” were the proxy predicate expressing a condition which specifies \( a \), then the valuated formula

(“\( Gx \)” under the assignment: \( a \) to ‘\( x \)’)

has as its surrogate

\[
(x)(Fx \supset Gx)^{72}
\]

Again we cannot indiscriminately rely on any arbitrary specifying conditions to serve as proxy since some may make the relativized surrogate logically true and others not.\(^{73}\) Essentialism again appears inevitable, since if “\( F \)” is any proxy predicate, the truth of the sentence

\[
(x)(Fx \supset Gx)
\]

which seems to say that the property expressed by “\( F \)” is essential to whatever has it, is ultimately defined by the truth of

\[
\Box (\alpha)(Fx \supset Fx).
\]

Quine hasn’t spelled out his argument in exactly this way, in terms of sur-
rogates for valuated formulas, but I think it may well be what he thought. At any rate, in connection with logical necessity it’s wrong. There is no need for surrogates. We can classify the logical truths among valuated formulas directly, as we have. And for this we needed no essence of Ortcutt other than Ortcutt.

A final point on the method of surrogates: I have been careful to hedge by saying that the method ‘appears’ to make essentialism inevitable. It doesn’t really. We can choose surrogates on any basis we like. Once we explain honestly how we are interpreting quantification, a kind of semi-substitutional interpretation, the question is no longer “Why do you think of that specification as essential to that individual?”, but is rather “What made you choose that specification as proxy for that individual?”. To which the answer may be, “Because I think it essential to her.” There’s the essentialism.

XVII

Perhaps the reason no Invidious Aristotelian Essentialism has shown up is that our weak logical necessity yields too anemic a modal theory to concern Quine. Quine expects the champion of modal logic to insist of nine that it is necessary greater than seven. So let us consider a case where I.A.E. appears by invitation. I suggest that, far from being foisted upon us by a desperate semantics, I.A.E. is entirely within our control and has its uses as a means to express widely shared, and justifiable, convictions about the natures of things.

Quine would not agree. Despite his careful advice to the modalist: to insist of nine, independently of mode of designation, that it is necessarily greater than seven, he continues to believe, in Marcus’s memorable phrase, “that modal logic was conceived in sin, the sin of confusing use and mention”, and he hints that the confusion, though not required of modal logicians, still sustains them. Moreover, he is confident that I.A.E. is wrong. He describes talk of a difference between necessary and contingent attributes of an object as “baffling—more so even than the modalities themselves” (the ‘objects’ he has been discussing are nine and Ortcutt). He says that one attributes this distinction to Aristotle. “But, however venerable the distinction, it is surely indefensible.” He seems highly sceptical that there could be reasonable arguments, even in limited cases, for I.A.E. It is such arguments that I now wish to take up.

Consider modalized set theory and the intuitively plausible I.A.E. claim that singleton Quine would not exist if Quine did not:

\[(x)(y)[(x = \text{Quine} \land (z \in y \equiv z = x)) \supset (\exists w)(w = x) \supset (\exists w)(w = y)]\]

We can argue for this claim by asking whether there are plausible alternatives, alternatives that allow singleton Quine to exist where Quine does not. One immediately thinks that if singleton Quine were to exist and Quine not, then singleton Quine would have no members. But there already is a set which has no members, the null set. Would singleton Quine then be identical with the null set? (Was singleton Quine identical with the null set on June 25, 1808?) Wouldn’t this violate:

\[(x)(y)((x \neq y) \supset (\exists w)(w = x) \supset (\exists w)(w = y))\]

If singleton Quine could be identical with a null set, could our own null set conceal distinct fused possibilia, say, the singletons of Quine’s merely possible seventh and eighth sons? Wouldn’t this violate:

\[(x)(x = y) \supset (\exists w)(w = x)\]

Maybe Quine’s singleton could be empty without becoming identical with any other thing. (It may appear empty because we count only ‘existing’ members.) Then there would be at least two (apparently) empty sets. This has the consequence that the axiom of extensionality is, at best, only contingently true, and probably not even that. Unacceptable!

So far, this little bit of reasoning—admittedly not definitive—has used only modest methods: some benign essentialism plus the necessity of the axiom of extensionality. It favors the conclusion that sets have their members essentially, at least in the weak sense:

\[(x)(y)[(x \in y \supset (\exists z)(z = x) \supset ((\exists z)(z = x) \land (x \in y))]\]

It wasn’t a proof, of course, but it should be responsive to the claim that (11) is ‘baffling’.

I think that (11) is true, but I am willing to listen to argument. The arguments may not be compelling, but I am convinced such arguments are legitimate. They turn on our understanding of the nature sets. The issues are metaphysical, not mere points of logic and certainly not mere confusions of use and mention. I studied section 4 of Mathematical Logic as a freshman, and taught it as a graduate student. Confuse use and mention? Me? Never!

My acquiescence in (11) and even my conviviality at argument for it do not imply that I regard every I.A.E. claim that can be expressed in the language of quantified modal logic as accessible to reasoning of a similar kind. Could Richard Nixon have been a turnip? This matter does not seem ripe for debate. It seems to call more for decision than for argument. Either decision will have consequences. This is a matter of (modal) logic. But I see little present reason to call one or the other decision correct.

XVIII

The logic of logical necessity is exhaustive, in the sense that for every sentence of the form \[\Box \phi\], either it or its negation is true in every model when \[\Box\] is interpreted as logical necessity (for the Sentences of that model). (And incidentally, this logic is not axiomatizable, for if it were, the non-theorems of first
order logic could be axiomatizable and thus the theorems decidable.) By its exhaustiveness, the logic of logical necessity excludes I.A.E. No matter how sympathetic to this goal, we can perhaps agree that rulings on I.A.E. should be a matter of metaphysics, not logic. What this shows is that I.A.E. makes its claim under an interpretation of "\( \square \)" other than logical necessity. (This we knew already, since logical necessity is benign.) Let us call this interpretation \textit{metaphysical necessity}. I would not attempt to characterize the truths of metaphysical necessity, but I will try to characterize its logic. I think that the logical features of metaphysical necessity are just these: truth and closure under logical consequence.\textsuperscript{79} This leaves it open that some metaphysician may assert that all truths are metaphysically necessary. It wouldn’t be the first time. And it wouldn’t be an abandonment of modality, just a peculiar doctrine about it, an extremely pervasive sort of metaphysical determinism. Logical closure and truth also leave it open that some metaphysician may assert that there are no metaphysically necessary truths beyond the logical truths. So be it.

If we use "\( [\Box] \)" to signify the logical necessity whose truth theory was given in section XIV, we can adopt "\( M \)" to signify the metaphysical necessity whose truths we debate. In a model, an appropriate extension for "\( M \)" is any set of first order sentences of the model that is closed under logical consequence and all of which are true in the model. \( M \) is bounded on the bottom by \( L \) and at the top by falsehood. It is not unreasonable, and it may be Quine’s position, to argue that there are no properly metaphysically necessary truths, briefly, that \( M = \Box \).\textsuperscript{80}

XIX

Quine’s first argument, involving the alleged theorem, was an argument against the intelligibility of the language of quantified modal logic. His argument charging invidious essentialism is not an argument against the intelligibility of the language; it is an argument against the truth of certain modal statements. In the "Discussion on the paper of Ruth B. Marcus,"\textsuperscript{81} he says, "I’m not talking about theorems, I’m talking about truth, I’m talking about true interpretation. . . . In order to get a coherent interpretation one has got to adopt essentialism . . . ."

The earliest appearance of Quine’s essentialism argument seems to be at the end of "Three Grades of Modal Involvement" (1953).\textsuperscript{82} There, Aristotelian essentialism is first broached in terms of essential rationality and accidental two-leggedness. We could formalize thus:

\[
(\exists x)(\Box x \text{ is rational} \cdot x \text{ is two legged} \cdot \sim \Box x \text{ is two legged})
\]

Heady stuff. Insofar as this form:

\[
(\exists x)(\Box \text{Fx} \cdot \Box \text{Gx} \cdot \sim \Box \text{Gx})
\]

is all there is to Aristotlean essentialism, quantified modal logic is infested. Since, as Quine quickly shows, if "\( P \)" stands for any contingent truth, it will be true that

\[
(E) \quad (\exists x)(\Box (x = x) \cdot (x = x) \cdot P) \cdot \sim \Box ((x \sim x) \cdot P)
\]

Clever, but hardly likely to quicken the pulse or, for that matter, to ‘baffle’ anyone. If this is a metaphysical jungle, then so is every logic classroom in Harvard University.

I cannot believe that benign essentialism of the kind exhibited in (E) could have been Quine’s target. His concern must have been that (E) opens the door to the heady stuff, to real I.A.E., not just to the ‘form’ of I.A.E. The argument charging essentialism must come down to this: (i) Adoption of a relational sense of necessity (or acceptance of quantification in) permits one to formulate I.A.E. claims. (ii) Those who adopt such a sense must wish to assert such claims. (iii) Such claims are unjustifiable. Viewed in this way the argument shows itself to be an \textit{ad hominem}: those who would foist this logic upon us are just the kind to foist some notorious falsehoods. This may well be true, but like other \textit{ad hominem} arguments it diverts attention from the details of the arguments at hand.

One aspect of Quine’s methodology has been used by some of his opponents. They too have based their investigations on attempts to syntactically characterize the ‘form’ of I.A.E. Model theoretic or proof theoretic methods are then used to demonstrate the presence or absence of theorems of this form in quantified modal logic.\textsuperscript{83}

My methodology goes the other way around. I develop what I take to be the intuitive notion of logical necessity \textit{qua} logical necessity, first from a model theoretic perspective and then independently by means of a reduction to non-modal first order logic. I then define as benign any essentialist sentence, however invidious its ‘form’, that is true in this theory.\textsuperscript{84}

I contend that in order to convince us that there is a metaphysical jungle in quantified modal logic, Quine would have to derive, from plausible premises (for example, that there are contingent truths), an essentialist statement that is incompatible with our theory of logical necessity. And since quantified modal logic, as ordinarily practiced, is compatible with our theory of logical necessity, that cannot be done.

The morals of our essentialist studies so far are these. The language of quantified modal logic can be interpreted without appeal to surrogates of any kind; thus, without appeal to essential names, whether tags or descriptions, other than variables. One fundamental theory of necessity, the theory of logical necessity, asserts no essentialism other than the benign Quinean kind. Even
Part D: CONTEXTUALITY

Because of their importance in the development of Quine’s thought about opacity, we must now digress to review some of his more recent views.

XX

In “Intensions Revisited”, Quine recognizes that relational senses of psychological verbs suffice to interpret quantification in. This leads not to reconsideration of the tenability of quantification in but to reconsideration of the tenability of the relational senses of psychological verbs. He had already charged that essentialism is required to interpret the relational sense of necessity. Now a seemingly parallel methodology leads to a seemingly parallel challenge to the relational sense of belief. This time the charge is *utter dependence on context*. Quine now thinks necessity and belief are quite parallel with regard to their relational senses. He asserts that even the notion of essence makes sense in context. I sense here the gathering forces of a new attack on quantification into opacity.

The discussion of contextuality begins by considering certain special, and what are to be taken to be central, cases of formulations involving relational senses. Cases we can represent with quantification in as:

\[(12) \exists x \; (x = \alpha)\]

and

\[(13) \exists x \; (\text{Ralph knows that } x = \alpha)\]

where \(\alpha\) is a singular term. Quine lays great importance on those singular terms \(\alpha\) which satisfy (12) and (13). He reads (12) as asserting that \(\alpha\) expresses an ‘essence’. He reads (13), following Hintikka, as asserting that Ralph knows who \(\alpha\) is. He then goes on to remark:

The notion of knowing or believing who or what something is, is utterly dependent on context. Sometimes, when we ask who someone is, we see the face and want the name; sometimes the reverse. Sometimes we want to know his role in the community. Of itself, the notion is empty . . . this leaves us with no distinction between the admissible and inadmissible cases of exportation . . . Thus it virtually annuls the seemingly vital contrast . . . between believing there are spies and suspecting a specific person. At first this seems intolerable, but it grows on one. I now think the distinction is every bit as empty, apart from context, as . . . that of knowing or believing who someone is. In context it can still be important. In one case we can be of service by pointing out the suspect; in another, by naming him; in others, by giving his address or specifying his ostensible employment . . . We end up rejecting *de re* or quantified propositional attitudes generally, on a par with *de re* or quantified modal logic. Rejecting, that is, except as idioms relativized to the context or situation at hand.

There is a sub-theme, almost a presupposition, in “Intensions Revisited” (reappearing in “Worlds Away”) that the availability of terms \(\alpha\) for which (12) and (13) are true is critical to our understanding of quantification in, and in particular to our understanding of the distinction between (3) and (4). With regard to the role of (12) in modal logic, Quine remarks “. . . the whole quantified modal logic of necessity . . . collapses if essence is withdrawn.” The suspicion that Quine is surrogate-minded grows.

Quine’s new thrust against quantification in develops as follows: We begin with the sub-theme of surrogatism. Sentences of the form (13) are then seen as indicating the surrogates, and thus as crucial. Next, by reading (13) in terms of the knowing-who idiom, it is made plausible that the choice of surrogates is utterly contextual. (And thus that contextuality infects all quantification in.) And finally, contextual relativity is assumed to imply the (ambivalent) rejection of “quantified propositional attitudes generally, on a par with quantified modal logic”. (More on ambivalence later.) I think each of the four steps is incorrect.

First let us clear the ground of surrogatism. It is clear that our methods do not require the use of surrogates, and indeed we used no surrogates to interpret quantified modal logic. Our classification of the logically necessary valuated sentences was in no way reductive, in no way dependent on a prior classification of the closed sentences. Second, even given the surrogate interpretation, not every name that satisfies (13) need be a proxy name. (In footnote 56 it was shown that if the attitudes are not closed under logical consequence, then contrary to Quine’s claim, (13) may not play the role for the attitudes that (12) plays for modality, namely to justify treating \(\alpha\) as an instanital term for quantification.) Third, although I have been convinced that knowing-who, in its most natural sense, is utterly dependent on context, this could not be the proper reading for (13). This takes a brief argument:

Quine acknowledges that quantified propositional attitudes do make sense relative to context. So pick a context to which to relativize. The following is a theorem of logic (no matter how we have relativized to context):

\[(\exists x \; \text{Ralph knows that } x = y) \supset (\text{Ralph knows that } x = y)\]

According to the proposed reading, logic tells us that if Ralph has noticed of a
certain man in a brown hat that he is self-identical, then Ralph knows who he is. Or, to put it in the contrapositive, if Ralph doesn’t know who you are, then he doesn’t know anything about you. (Note that if he knows anything about you, he knows that you are self-identical.) This could not be correct. We went wrong in thinking that the benign 
\( (\exists x) \text{Ralph knows that } (x = y) \)
says, in the natural sense, that Ralph knows who \( y \) is.

**XXI**

I believe there is a significant use of the idioms symbolized by quantification into propositional attitudes which is not dependent on context. When Ralph saw Ortcutt in his brown hat behaving suspiciously, I think Ralph came to believe of Ortcutt that he was a spy, and this despite the fact that he didn’t know, in any helpful way, who Ortcutt was. However, I will not argue that point. Instead, I will address as the main issue, the *consequences of dependence on context, assuming it exists.* Should we reject, at least for purposes of constructing a logic, a form of language in which truth is dependent on context?

I want to discuss dependence on context within a framework of critical notions which, I rush to acknowledge, I do not understand well. I aim for a useful, rough cut.

We need a better understanding of the different ways in which the ‘meaning’ (in a very loose sense) of a linguistic form may seem to vary from utterance to utterance and of the liabilities of each of these styles of inconstancy. For example, we are told that what counts as knowing who a is, knowledge (like “bank”), a theoretical term (like “intelligent”), or what? Whatever the ultimate analysis, such variance in ‘meaning’ must raise the possibility of *equivocation,* the assignment of different ‘meanings’ to the same linguistic form within the same discourse. Let us assume that the linguistic forms with which we are concerned are *contextually determinate,* in the sense that their ‘meaning’ is determined by the context of their utterance. And let us suppose that the sentences in which these forms occur are otherwise sufficiently well behaved that there is a *relativized notion of truth with respect to a context of utterance* for them. 89

There is an important methodological point to be made. A relativized notion of truth is no impediment to the construction of a logic. Logic aims to preserve truth. If truth varies with context, logic must preserve truth for each context. It goes without saying that premises and conclusion must be relativized to the same context. To do otherwise would be to commit the fallacy of equivocation. Logic abhors equivocation; it does not abhor a relativized notion of truth.

I earlier mentioned Quine’s “ambivalent rejection” of quantified propositional attitudes. On my reading of “Intensions Revisited,” Quine accepts a relativized notion of truth for these idioms. Each denunciation of the absolute emptiness of the idioms is balanced by acknowledgment of their relativized seemliness. This is the ambivalence I saw. If this is the correct account of Quine’s views, then there is no argument against a modal logic.

Quine is certainly aware of the methodological point. But he doesn’t seem to come to grips with the way in which it conflicts with his idealization of eternal sentences. 90 For example, in section III of “The Scope and Language of Science” 91 he argues that deductive logic is simplified and facilitated if we rid our language of indexicals. The reason given seems to be that a sentence containing indexicals could change truth values between its appearance in a premise and its appearance in the conclusion. (Does this reflect a strangely concrete conception of the constituents of a logical argument? Is logic about tokens?) However, in the very next paragraph there is a tentative turnabout. He points out that “in practice one merely supposes all such points of variation fixed for the space of one’s logical argument . . . .” (Why only in practice; why not in theory?) And again in *Word and Object* page 227 he clearly states, “We do apply logic to sentences whose truth values vary with time and speaker”, and he warns of the fallacy of equivocation. (This time he is right on the money.)

Let us suppose that it was never the logic of contextually determined expressions that exercised Quine, it was always their theory of truth (as he says in the passage quoted at the beginning of section XIX). Here, I think he is simply too indiscriminating in rejecting the contextually determined.

The most straightforward way in which the contribution of a linguistic form may be determined by context is for the linguistic form to make explicit reference to, or other explicit use of, features of context. This is the way in which the indexicals: “I”, “today”, “here”, etc. are contextually determinate. The indexicals are *explicitly contextual.* A pronoun whose antecedent lies within the context of the discourse, but beyond the sentence in which the pronoun occurs, is also explicitly contextual. It is not entirely trivial to develop the logic for a language containing indexicals, but it is clear that there is one. 92 The same holds for the theory of truth for such a language. I have no trouble with explicit contextuality. It is at worst benign, at best indispensable.

Is the same true of the *implicitly contextual?* In order to see how implicit contextuality affects logic, consider two cases of implicit contextuality involving ambiguity. Suppose that the ambiguity of “checks” were always completely resolved by context. (Perhaps by the discourse context, whether we are discussing haberdashery or finance; perhaps by the speaker’s intentions, if that
is a legitimate part of context.) And suppose that the referential ambiguity of "President John Adams" were always completely resolved by context. (Not necessarily by the intentions of the speaker but perhaps by his connections.) Oddly enough, it is trivial to develop the logic of a language containing this kind of ambiguity. The injunction not to equivocate in the course of an argument makes the ambiguities disappear for logical purposes. Logic is unaffected by this kind of ambiguity.

Still, implicit contextuality is troubling from the point of view of truth. Implicit contextuality seems misleading in a way that explicit contextuality is not. One wants to say, mimicking Frege, "So long as there is contextual determination such variations in sense may be tolerated, although they are to be avoided in the theoretical structure of a demonstrative science and ought not to occur in a perfect language."

I think that Quine and I share discomfort with what I have called implicit contextuality, and would not like to see it appear in austere scientific language. (Though I think it is probably unavoidable.) However, Quine's conception of proper scientific language seems to lead him to want to avoid even explicit contextuality.93

What is the nature of the contextuality that Quine finds in the quantified propositional attitudes (and in quantified modality as well)? Let me try to formulate a Thesis of Contextuality I see in "Intensions Revisited":

When we attribute a relational attitude to someone, the truth of our attribution may depend not only on the person's circumstances but on ours, in particular, on the purpose and context of the discourse in which we make the attribution.

This sounds like a thesis of implicit contextuality. And if so, and if true, it is unfortunate. (I am undecided whether it is true.94) But there is so much of that sort of thing going around nowadays, that it shouldn't provoke an agony of self-doubt. (Remember, even Quine was ambivalent.) As we have already seen, contextuality is no bar to our studying the notions involved with the tools of logic. I believe that with the possible exception of a few bridge laws, the logic will turn out to be the same for all contexts anyway. These studies should proceed.

Part E: TECHNOLOGY AND INTUITION

We now return to the main line of argument.

XXII

There are historical reasons that help to account for Quine's attitude toward opacity. The contexts he first investigated were quotation contexts and modal contexts. He reports early arguments with C. I. Lewis and E. V. Huntington over the interpretation of modal logic, arguments in which "I found it necessary to harp continually on the theme of use versus mention."95 The quotation context was seen as the paradigm of opacity. This makes the alleged theorem plausible. Quine's outlook from the early period when he began his long and fruitful studies of opacity is summed up in R&M:

It would be tidy but unnecessary to force all referentially opaque contexts into the quotational mold; alternatively we can recognize quotation as one referentially opaque context among many.

At least since the time of "Intensions Revisited", Quine has known that if there is any opacity producing phrase with a legitimate relational sense, the alleged theorem is false. But he remains suspicious. His old essentialism challenge to the relational sense of necessity has been joined by a new contextuality challenge to the once secure relational senses of propositional attitude idioms.

What is the bearing of our results on Quine's doubts?

We have outlined some technological innovations (arc-quotation, valuated sentences, etc.) that promise to remove technical obstacles to quantification into arbitrary opaque contexts (arbitrary, in not requiring closure conditions).96 The alleged theorem, which provoked the technological research, posed a technical objection to quantification in. So we have shown that quantification in is technically feasible.

We have done a bit more than that. We have contrasted two conceptions of the objects of intensional operators, and thus two conceptions of opacity. We have attempted to link our technology to a grand, historical, philosophical tradition, and to contrast that tradition with another grand, historical, philosophical tradition, one with which we associate Quine's doubts.97 In this way I hoped to bring a larger philosophical perspective to bear, or, more accurately, to open the door to bringing such a perspective to bear. I know from my own case how powerful the arguments showing the inadequacies of Frege’s outlook can be in dispelling a certain simple and intuitively appealing conception of opacity. Quine's doubts are not exactly Frege's. Quine is so much less theory bound, so much more 'experimental' in philosophical temperament. But his paradigm of opacity, quotation, is structurally similar to Frege's. And a paradigm may be all the difference there is between the natural and the artificial.

And we have done one thing more in a positive direction. We have argued for the intuitive reasonableness of one theory of quantified modality and the not unreasonableness of some others. But how much intuition and reasonableness can be brought to bear on a topic like modality?98

Beyond that we have played the traditional defense: drawing of distinctions, counter-instances, blocking moves, etc. I question the efficacy of these moves. They may defeat arguments; they rarely exorcise doubt.
What more is there to say to someone who still feels that there is something wrong with all those operators that are blithely said to be true of valuated sentences, something that is hard to put your finger on, but having to do with a promiscuous extension of the basic notional intuitions associated with the operator, the kind of promiscuous nonsense that would appear if we slipped the interpretive constraints of our direct discourse operator *Says-quote* and began regarding some quantifications in as true?

Our technology is neutral. It cannot insure against that sort of nonsense (or that sort of *falsehood* as we earlier termed it). On the other hand, it also cannot insure against arbitrary constraints that limit all operators to a notional core; it cannot force surrender of the hard line. Technology cannot insure against bad philosophical judgment. Nothing can.

What then remains to be said to instinctive hard-liners? We can try to exhibit an easy, highly intuitive case of quantification into opacity about which there are no legitimate doubts. In this way we aim to show that even beyond technology, there can be no general *philosophical* argument in favor of the hard line. With the hope that intuition will be more compelling than sophisticated technology, we also aim to nudge the intuition of the hard-liners away from the paradigm of quotation toward a new paradigm of opacity.

**XXIII**

Suppose Quine had begun his studies of opacity not with quotation and modality but by studying temporal operators. Consider, for example, "It will soon be the case that", which we abbreviate "S". Temporality involves non-purely referential occurrences of names just as surely as do necessity and belief. We may assume it true that

(14) \( S(\text{the President of the United States is a woman}) \)

It is also true that

(15) The President of the United States = Nancy Reagan's spouse

But it is highly unlikely that

(16) \( S(\text{Nancy Reagan's spouse is a woman}) \)

Thus, substitutivity fails. Contexts of S are opaque. Now what about quantification? Let us consider:

(17) \( (\exists x)(x \text{ is a child } . \ S(x \text{ is a woman}) \)

Typically, Quine would ask, who is this child who will soon be a woman? Is it, as (14) suggests, the President of the United States, that is, Nancy Reagan's spouse? But to suppose this conflicts with the fact that (16) is false.

Does the apparent intelligibility of (17) therefore commit us to a jungle of temporal essentialism or utter dependence on context? Certainly not. Being the President of the United States need not currently characterize the individual whom it will characterize when, according to (14), she is President, and being a woman is also a fugitive property. The intelligibility of (17) is quite independent of any surrogates including the singular terms of (14) and (16).

As to temporal essentialism, there are those who say that there are eternal properties (that is, properties which are temporally essential), and they might offer: being human (here, some Aristotelian-like essentialism), being Nancy Reagan (a not purely-qualitative property), or being President of the United States in 1984 (a 'time indexed' property). There is much to say about the metaphysical views according to which being human is temporally essential and being Nancy Reagan or being Nancy Reagan's spouse in 1984 are properties at all. I have said some of it. The important point is that such sophisticated matters, including the existence of not purely-qualitative properties, let alone their expressibility in the language of temporality, are quite irrelevant to our ability to understand (17). Indeed, if we could not already understand sentences such as (17), how could we even formulate the claims of these temporal essentialists? The intelligibility of quantification is *prior* to the acceptance (or rejection) of essentialism, not tantamount to it.

Let me sum up the case of quantified temporal logic. Substitutivity fails, thus opacity reigns; quantification receives its standard interpretation; quantification in offers no problems of intelligibility (neither logico-semantic nor metaphysical); the interpretation of quantification in requires no surrogates, no invidious distinctions among ways of characterizing an object; the interpretation is not dependent on context; and finally, for you stubborn object fans, the objects can be characterized in inequivalent and fugitive ways. We do, of course, accord a special place to the purely referential role of variables, but we need not have any other way of specifying an object which is especially 'germane' to the question whether the object satisfies a formula containing a free variable within a temporal context. Thus we see, in a single case: counter-instances to the alleged theorem as well as to many 'philosophical' sorrows that have been thought to result from quantification into opacity.

Here is just a bit of sophisticated analysis as to what makes quantification into temporal operators work. You may think it depends on a doctrine of enduring objects. It doesn't. It depends on the doctrine that it is meaningful to ask of our objects, enduring or not, what properties they will or did have at other times. And we must, of course, ask this of the object itself, independent of any particular form of specification. To see this, think of the rich realm of temporal truths regarding long enduring heirlooms like Maytag washing machines and Mercedes Benzes. Now imagine that the lives of these individuals grow progressively shorter, perhaps due to a declining standard of workmanship. The temporal truths become more boring. Suppose that ultimately, like some elementary particles, they come to last for only a moment. There would then be little reason to want to discuss their future and past (they have none,
in a certain sense), but it would still be meaningful to do so. There would no longer be those interesting invidious temporal truths, but the language and its logic would still be impeccable (though useless, as is so much that is impeccable).

There may be sophisticated disagreement about what makes quantification into opaque temporal contexts work, but it does work. And that’s a fact. I cannot help but think that had Quine turned his attention in 1942 first to reference and temporality (before modality and before quotation), the recent history of semantics would have been quite different. I hope we soon learn what Quine now thinks about the bearing of temporality on the problem of quantification into opacity. How I wish we could know what Frege would say about it.

The purpose of this volume is not to praise Quine, but to query him. Still, having said so much in dispute, and so much that he will want to dispute, I wish to add what is indisputable, that tracking his thought is constantly enlightening and a continual delight.

Appendix A: Paraphrasing into Propositional Attitudes

The tenability of the transformations which carry intensional verbs that do not take sentential complements—like the notional sense of “wants (a sloop)” and “seeks (the author of Waverly)”-into compounds in which the main verb does take a sentential (or ‘propositional’) complement—like “wishes that one has (a sloop)” and “strives that one finds (the author of Waverly)”-is critical not only for Quine’s analysis but also for the tradition of analyzing such constructions in accordance with Russell’s theory of descriptions. Without an inner sentential context, Russell’s distinctions of scope disappear, as do Quine’s. And with them goes the thesis, so dear to Quine, of the first order eliminability of singular terms other than variables.

But it is not obvious that such transformations can always be made with preservation of meaning, not even if we take preservation of meaning to be so weak a thing as necessary equivalence.

If, as Quine claims in the opening sentence of Q&PA, the incorrectness of rendering “Ctesias is hunting unicorns” in the fashion

\[(\exists x)(x \text{ is a unicorn} \land \text{Ctesias is hunting } x)\]

is conveniently attested by the non-existence of unicorns, then similar considerations may attest to the incorrectness of rendering “The Greeks worshiped many gods” as

\[(\forall x)(x \text{ is a god} \land \text{the Greeks worshiped } x)\]

or “The Greeks worshipped Zeus” as

\[(\exists x)(x \text{ is-Zeus} \land \text{the Greeks worshipped } x)\]

But how shall “worships” be transformed into a propositional attitude? (The point—that such examples pose a problem for analyses by Russell’s theory of descriptions—is originally due to Alonzo Church. The example is from Kamp, one of four cited by Montague.)

And when a hunting accident so traumatizes Ctesias that he comes to fear unicorns (not, to fear that there are unicorns or that he will encounter a unicorn, but to have a true unicorn phobia—one that has begun to ‘generalize’ to take in horses and antelopes), what propositional attitude will capture his psychological state? “What is it that you fear will happen?”, we ask Ctesias. “Nothing”, he replies. “I just don’t like unicorns.” Now it may be that even in this case there is some expression of Ctesias’ fear in terms of his propositional attitudes (perhaps from a behaviorist perspective). But it would certainly be surprising if on the basis of an a priori linguistic analysis, it were possible to establish such a far-reaching conclusion about the grammatical form of the primitive predicates of cognitive psychology.

There is also the complication (noted in footnote 7) that hidden relational senses of psychological verbs may appear when notional senses of psychological verbs are paraphrased into the propositional attitude idiom. In some of these cases, a theory of indexicals or quasi-indexicals will not suffice. For example, the notional sense of “I seek a lion” seems to be more adequately rendered by:

\[I \text{ strive that } (3x)(x \text{ is a lion}) \land I \text{ find } x\]

than by Quine’s formulation which omits the relational use of “recognizes” and adopts an extensional use of “find”. If a lion seeker does not recognize the object he perceives close at hand (i.e., ‘finds’ in the extensional sense) to be a lion, he will not have satisfied his striving. Here again it may be possible to find a remedy (perhaps by moving “I recognize that” to the front of the quantifier), but the matter is delicate.

There is another course. We could give up the attempt to paraphrase all the psychological opaque constructions in terms of propositional attitudes. We would lose the striking contrast between (3) and (4). We would lose the utility of elementary logic in representing internal structure for all the notional senses (for example, to represent the difference between wanting a sloop and wanting all the sloops). And, of course, the adherents of Russell’s theory of descriptions would lose their confidence that their theory could solve all of the logical problems of opacity. What would we gain? First, surcease from what I believe to
be a vain attempt, and the marginal benefits that sometimes accrue from facing reality. Second, an appreciation for some of the subtlety and utility of higher order intensional logics in providing entities for “at least one sloop” and “every sloop” to mean.

Montague took exactly this course in “The Proper Treatment of Quantifiers”. Russell insisted, in “On Denoting”, that such phrases had no meaning in isolation, but in the higher order intensional logic of Principia Mathematica he developed the means of providing that meaning. In Church’s “Outline of a Revised Formalization of the Logic of Sense and Denotation” such meanings would be the senses of the expressions:

“\( \lambda f (\exists x)(x \text{ is a sloop } . f x) \)” and “\( \lambda f (x)(x \text{ is a sloop } \supset f x) \)”.

Appendix B: The Syntactically De Re

In English we have no equivalent in a pedantic de dicto form: “It is not the case that Ortcutt is a spy”, as well as in the more colloquial de re form: “Ortcutt is not a spy”. Corresponding to the de dicto modality: “It is possible that Ortcutt is a spy”, we have the adverbial de re “Ortcutt possibly is a spy”. And corresponding to the de dicto attitude: “Ralph believes that Ortcutt is a spy”, we have the passive + infinitive de re: “Ortcutt is believed by Ralph to be a spy”. I speak here of unproblematical matters of English syntax. I acknowledge that the semantics of these English forms is problematical. Still, the syntactically de re has long been used (at least since 1358) to explain the semantically de re. In formal systems the semantically de re has usually been represented by quantification into the syntactically de dicto. Driven by the alleged theorem, Quine introduced a formal version of the syntactically de re in QPA (where he calls it a ‘relational sense’). I think it interesting and important to study these forms in their own right, their misconception notwithstanding.

Let \( O \) be a syntactically de dicto sentential operator. Then, if \( \Gamma \) is a formula (open or closed), \( O\Gamma \) is a formula (open or closed, according as \( \Gamma \) is). Quantification into the syntactically de dicto is permitted. (“[ ]” is a typical syntactically de dicto sentential operator.) The syntactically de re operator also takes a formula as its operand, but rather than forming a formula it forms a compound predicate. It does this, in the manner of the \( \lambda \) operator, by binding variables to produce new argument places. The degree of the compound predicate (monadic, dyadic, etc.) is determined by the number of variables bound by the de re operator. If \( v_1, \ldots, v_n \) are distinct variables, \( \Gamma \) is a formula, and \( \alpha_1, \ldots, \alpha_n \) are terms, then \( O \) is the de re variable binding operator corresponding to \( \alpha_1, \ldots, \alpha_n \) is an n-place de re variable binding operator phrase, \( [(Ov_1 \ldots v_n) \Gamma] \) is an n-place predicate expression, and \( [(Ov_1 \ldots v_n) \Gamma ] \alpha_1 \ldots \alpha_n \) is a formula. Free occurrences of \( v_1, \ldots, v_n \) in \( \Gamma \) are bound by the operator, whose scope extends just to the end of \( \Gamma \). We need not require that \( v_1, \ldots, v_n \) include all of the free variables of \( \Gamma \).

Quine’s original motive for introducing the syntactically de re was to use it to express, in a less ‘dubious’ form, quantification into the syntactically de dicto. However, in suggesting how to translate from the syntactically de dicto into the syntactically de re he committed a subtle error. Recall Ralph’s situation. He has seen Ortcutt twice, under different circumstances, and not recognized him as the same person. Thus Ralph may have de re beliefs relating Ortcut (seen in a brown hat) to Ortcut (seen at the beach). For example, he may believe that the former is taller than the latter. Now this presents a problem for the syntactically de dicto, since there is no way, without additional logical resources, to distinguish a report of this de re belief from a report of the absurd de re belief about Ortcut that he has the monadic, reflexive property of being taller than himself. The problem is that:

\[
(18) \quad (\exists y)(\exists z)(y = z \cdot Bel (y \text{ is taller than } z))
\]

is logically equivalent to:

\[
(19) \quad (\exists y) Bel (y \text{ is taller than } y)
\]

(where “Bel” abbreviates “Ralph believes that”). If, however, we use the syntactically de re, we can easily distinguish these beliefs. Ralph’s situation is this:

\[
(20) \quad (\exists x)((Bel yz) \text{ y is taller than } z \cdot x)
\]

where “y” and “z” have the same value? Do we understand it as:

\[
(21) \quad (\exists x)((Bel yz) \text{ y is taller than } y \cdot x)
\]

and these two are not logically equivalent. Quine’s proposal translates (18) into a formula equivalent to (20), and (19) into (21). One of these translations must be incorrect, since equivalent formulas could not translate into inequivalent ones.

Here is the heart of the matter. How do we understand

\[
(22) \quad Bel (y \text{ is taller than } z)
\]

when “y” and “z” have the same value? Do we understand it as:

\[
(23) \quad [(Bel yz) \text{ y is taller than } z \cdot yz]
\]

or as:

\[
(24) \quad [(Bel yz) \text{ y is taller than } y \cdot yz]
\]

(Note that since the scope of the operators ends at the right bracket, the final occurrences of “y” and “z” in (23) and (24) are free.) Since we do not, in general, know when distinct variables have the same value, it seems that an understanding of (22) which would be uniform for all values of “y” and “z” should favor (23) over (24). If we do translate (22) into (23), then in view of the equivalence between (18) and (19),

\[
(25) \quad Bel (y \text{ is taller than } y)
\]

should translate into

\[
(26) \quad [(Bel yz) \text{ y is taller than } z \cdot yy]
\]
rather than into (24). (18) and (19) would then translate into equivalent formulas, as they should. The subtlety in translating the syntactically de dicto into the syntactically de re lies in the translation of (25) into (26). When a free variable has more than one occurrence in the operand of the syntactically de dicto form we must first articulate the operand by eliminating repetitive de re occurrences of variables.

Let the free variables of \( \Gamma \) be \( w_1, \ldots, w_j \) (some of which may have more than one free occurrence in \( \Gamma \)). We replace each free recurrence (after the first free occurrence) of a variable with a free occurrence of the alphabetically first new variable. Let the free variables of the result, \( \Gamma^* \), be \( v_1, \ldots, v_j, \) each of which will have exactly one free occurrence in \( \Gamma^* \). Let the replacement be such that replacing free occurrences of \( v_1, \ldots, v_j \) in \( \Gamma^* \) with \( u_1, \ldots, u_k \) respectively restores \( \Gamma \) to \( \Gamma \). (Example: let \( \Gamma \) be \("\text{Rxxy}"\). Then \( w_1, \ldots, w_n \) are \("x", "y", "z"; \( \Gamma^* \) is \("\text{Rxyz}"\); \( v_1, \ldots, v_n \) are \("x", "y", "z"; \( u_1, \ldots, u_n \) are \("x", "y", "z"\).) In the second step we translate as follows:

\[
\Omega^* \iff [(O\Gamma_1 \ldots \Gamma_n)]^{\Gamma^*} u_1 \ldots u_n
\]

(In our example, \( ORxy \iff [(O\text{Rxy})] xy \) ) Note that the de dicto form and its translation have the same free variables. If \( \Gamma \) has no free variables, \( \Gamma^* = \Gamma \), and we have a degenerate case of the syntactically de re: \( \Gamma^* = \Gamma^* \).

The question of adequacy for a translation depends upon the operator involved. When \( \Omega \) is \("Bel"\), the inequivalence of (24) and (25) shows that:

\[
(x)[(O\text{Rxy})] xx \iff [(Ox)\text{Rxx}] \quad x
\]

fails.108 Hence articulation is required when translating the syntactically de dicto form of \( \text{Bel} \) into the syntactically de re. (And similarly for the other attitudes.) Although they translate no syntactically de dicto formula, syntactically de re formulas like the right hand side of (27) (let like (21)) are grammatically correct. This suggests that the syntactically de re has more expressive power than the syntactically de dicto. But suppose that \( \Omega \) were the syntactically de re form of \( \Box \) or of the S of temporality. One would then expect (27) to hold. (Since Ortcutt and Ortcutt could not stand in the relation R unless Ortcutt were to have R to himself.) Hence one need not be so fastidious about articulation for \( \Box \) and \( S \). (Though I would still regard the two sides of (27) as differing in meaning.)

Do not think that the recalcitrance of (27) for \( \text{Bel} \) is due to any logical deficiency on Ralph's part. Even if Ralph were logically omniscient, (27) would still fail from left to right; though in my view it would hold from right to left.109 This difference between the de re forms of what I am wont to call 'metaphysical' operators (modality, temporality) and what I call 'epistemological' operators (psychological attitudes, etc.) even as applied to the logically omniscient, marks an important distinction between the form of logical consequence under which, say, the modalities are closed and the form of logical consequence under which, say, logically-omniscient-belief is closed. If Ortcutt were correctly introduced to Ralph as 'the Mayor', and later, not recognizing him to be the same person, Ralph were to observe him behaving suspiciously, it could well be the case that:

\[
(28) \quad (\exists x)(x = \text{the Mayor}) \cdot \text{Bel} \quad (x = \text{the Mayor}) \cdot x \text{ is a spy})
\]

But no amount of reasoning on Ralph's part, though he be logically omniscient, could bring him to:

\[
(29) \quad \text{Bel} \quad (\text{the Mayor is a spy})
\]

The failure of this inference reinforces the point made in footnote 56 that \( (\exists x) \text{Bel} (x = \text{the Mayor}) \) does not suffice to make "the Mayor" an instant term.110 Note that if Bel were replaced by one of the metaphysical operators the inference from (28) to (29) would go through.

We can sum up the logical situation by isolating three pairs of principles (in each case the second is simply the converse of the first):

### Abstraction:

\[
\Omega^* \supset [(O\Gamma_1 \ldots \Gamma_n)] \quad \Gamma^* \supset u_1 \ldots u_n
\]

(Example: \( ORxx \supset [(Ox)\text{Rxx}] \quad x \) )

Concretion:

\[
\Omega \supset [(O\Gamma_1 \ldots \Gamma_n)]^{\Gamma^*} u_1 \ldots u_n
\]

(Example: \( ORxx \supset [(Ox)\text{Rxx}] \quad x \) )

### Articulated Abstraction:

\[
\Omega^* \supset [(O\Gamma_1 \ldots \Gamma_n)]^{\Gamma^*} u_1 \ldots u_n
\]

(Example: \( ORxx \supset [(Ox)\text{Rxx}] \quad x \) )

### Articulated Concretion:

\[
\Omega \supset [(O\Gamma_1 \ldots \Gamma_n)]^{\Gamma^*} u_1 \ldots u_n
\]

(Example: \( ORxx \supset [(Ox)\text{Rxx}] \quad x \) )

### Reflexivization:

\[
[(O\Gamma_1 \ldots \Gamma_n)]^{\Gamma^*} u_1 \ldots u_n \supset [(O\omega_1 \ldots \omega_n)] \quad \Gamma^* \supset w_1 \ldots w_n
\]

(Example: \( (Ox)\text{Rxx}] \supset [(Ox)\text{Rxx}] \quad x \) )

### Reflexive Elimination:

\[
[(O\Gamma_1 \ldots \Gamma_n)]^{\Gamma^*} u_1 \ldots u_n \supset [(O\omega_1 \ldots \omega_n)] \quad \Gamma^* \supset w_1 \ldots w_n
\]

(Example: \( (Ox)\text{Rxx}] \supset [(Ox)\text{Rxx}] \quad x \) )

Reflexivization: The converse of Reflexivization

The first pair (Abs/Con) is equivalent to the conjunction of the second pair (Articulated Abs/Con) and the third pair (Reflexive Intro/Elem). I proposed Articulated Abs/Con for translating the syntactically de dicto into the syntactically de re. I believe that Reflexive Elimination holds for modal and temporal operators as well as most of the familiar propositional attitudes (though the case of the attitudes is a bit complicated). This puts the focus of attention on Reflexivization. The inadequacy of Abs/Con as a translation of the propositional attitudes from the syntactically de dicto into the syntactically de re can be localized in Reflexivization. Similarly, the satisfaction of Reflexivization by modal and temporal operators implies that Abs/Con is an adequate translation scheme for them, and thus that the syntactically de re offers no greater expressive power than the syntactically de dicto for such operators.

Even in the case of the attitudes, the question of relative expressive power is somewhat delicate.111 It is natural to consider translating the syntactically de re back into the syntactically de dicto thus:

\[
[(O\omega_1 \ldots \omega_n)] \quad z_1 \ldots z_j \iff \Omega \quad (\exists z_1 \ldots \exists z_j)(\Sigma (w_i = z_i) \quad \Gamma)
\]

where \( \Sigma (w_i = z_i) \) stands for the conjunction of all \( \Gamma (w_i = z_i) \) for \( i \leq j \).

(Example: \( [(Ox)\text{Rxx}] z \iff \Omega (\exists x)((x = z) \quad \text{Rxx}) \) )

were the syntactically de re marks an important distinction between the form of logical consequence under which, say, the modalities are closed and the form of logical consequence under which, say, logically-omniscient-belief is closed. If Ortcutt
The difficulty with such a scheme lies in the implied inner existential import. I
may wish of you that you didn’t exist, without wishing that you were an exist­
ing thing that didn’t exist. Or, mistakenly thinking you to be an apparition, I
may believe of you that you don’t exist, without believing that you are an exist­
ing thing that doesn’t exist. 112

I see no way to interpret (i.e. translate) the syntactically de re attitudes
within the syntactically de dicto (without increasing the expressive power of
the syntactically de dicto). 113

There are still further reasons for liking the syntactically de re. As Richard­
ard has shown, we can use a variant of it to express what Lewis has called
belief de se—roughly, the beliefs one expresses about oneself through the use
of the first person. 114 We write ‘‘[(Bel xy) ~ x spied on y] Ralph y” to
report the belief voiced by Ralph’s indignant denial to y: “I did not spy on
you.” 115 This suggests a more perspicuous notation, ‘‘[(Bel T xy)]”, in which we
exhibit the pronoun. We might generalize to ‘‘[(BelT 27w xy)]” and even to
‘‘[(BelHesperus xy)]”, thus allowing a bit of direct discourse to mix with the
nihilist.

There is so much more of logical interest to say about the syntactically de re,
that I will say no more. Except to ask where our seeming inability to trans­
late the syntactically de re into the syntactically de dicto and our difficulties
(involving articulation) in translating the syntactically de dicto into the syntact­
cally de re leaves ‘‘the logician’, with his casual trick of re-ambiguation? He
hedged. (“If we can . . . transform each logically dubious formulation into a
unique indubitable one . . . ”) And he was vague. (He didn’t say how the
transformation went for the difficult cases, which involve multiple occurrences
of the same externally bound variable.) His concern was the same as Quine’s:
Is it legitimate to quantify into the syntactically de dicto, or must a new syn­
tactical form be created to express what was attempted by quantification in?
The expressive power of the new syntactical form was not at issue for him.
He’s O.K.

In 1968 I made the vague claim that the syntactically de dicto could repre­
sent the syntactically de re with “no loss to Quine’s theory.” (I, also, didn’t
say how.) Did this mean with no loss to the expressive power of the syntacti­
cally de re? Alas, it probably did. Not good.

In 1977, Quine, abjuring vagueness, proposed to show precisely how to
represent the syntactically de re within the syntactically de dicto, and suc­
cumbed to the risk of falsifiability. 116 Dangerous business!

Appendix C: ARCS VERSUS CORNERS

Arc-quotations names turn out to name exactly what they should name: a con­
catenation of the ‘‘closed” part of the quoted material with the individuals that
are the values of the bindable occurrences of variables. If variables occurring
within a form of quotation marks are to be regarded as bindable, this seems the
inevitable result. Using ~ to indicate concatenation:

(30) (y) (ex x exceeds y) = (“(ex) x’’ ~ y” exceeds “x’’)

Quine also has introduced a device, corner-quotes, for quantifying into quo­
tation.

(31) (a) [”(ex) a exceeds x” = (“(ex) a ~ x” exceeds “x”)]

Quine restricts the values of his variables to traditional expressions; I
have removed this artificial restriction. Quine syntactically distinguishes his
bindable occurrences of variables by font, using Greek letters; I use the italic
Latin letters of the object language and syntactically distinguish my bindable
occurrences of variables in the traditional way, by freedom. 117 When α is
“Quine”, “(ex) α exceeds x” is a traditional true sentence. When y is Quine,
“(ex) y exceeds x” is an untraditional true sentence. As I have argued
above, for the purposes at hand—semantical purposes—the untraditional sen­
tences serve shoulder to shoulder with the traditional.

Scientific candor compels me to acknowledge that there may be disanalogies
between closed and valued sentences. Both are, of course, types, but do valu­
ted sentences have tokens? 118

Thought of in terms of (30) and (31), it would seem that if the value of the
variable “y” were an expression (in the traditional sense), then my arcs would
amount to Quine’s corners.

(y = α) ⊃ (“(ex) y exceeds x” =’exceeds x’”)

This is not correct. When the value of “y” is “Quine”, “(ex) y exceeds x”
is not the traditional true sentence. It is the untraditional true sentence which
asserts of the object “Quine” (with all its vowels) that it exceeds something.
Otherwise there would be an ambiguity in our notation whenever the value of
the variable is an expression. This shows that we must revise our formulation of
(30). Our metaphorical use of “concatenation” to describe the relation be­
tween object and predicate in a valued sentence cannot be expressed by an
extension of the ordinary concatenation notion, ~, since when the object is an
expression we must distinguish the traditional concatenation of it (qua expres­
sion) with the predicate, from our new form of ‘concatenation’ of it qua object
with the predicate. For that matter, we must also distinguish treatment of the
predicate qua predicate from its treatment qua object. (A reason for focusing
on the subject is that if the predicate is treated as an object, the resulting
valued expression will not be well formed.) Let us, therefore, adopt bracketed
concatenation, { }, to mark the object places.

(y) [(ex) y exceeds x] = (“(ex) x’’ y” exceeds “x’’)

The primary difficulty, of course, was not with our notation, it was with
our intuitive representation of valued sentences as sequences of expressions
and objects. This representation is inadequate in that it does not distinguish
those of its component expressions that are to be regarded as expressions from those that are to be regarded as objects. We thus have a kind of logical imperfection in our syntactical representations.\textsuperscript{119} The new notation suggests a way out. Instead of embedding the 'objects' differently from the 'expressions', mark the entities which are to be regarded as objects in such a way that even if they were expressions before marking, after marking they no longer will be.

Here is the moral: my arcs are a complement to Quine's corners, not a replacement for them.

Appendix D: THE SECOND LAW OF IDENTITY

Several authors, seemingly emboldened by their awareness that substitutivity does not hold in general in opaque contexts, have announced formalisms in which they casually reject instances of the second law of identity, especially those instances of the form:

\[
\text{ID2} \quad (x)(y)((x = y) \supset (\Gamma xx \equiv \Gamma xy))
\]

with the variables occurring within an opaque context in \(\Gamma\). (Their thought seems to be that distinct variables can carry the same individual off in different directions.) It is they whom Quine justly accuses of wantonness. However, it is possible to reformulate the second law of identity so that it is no longer a principle of substitutivity. By this I mean that the second law need not involve any replacements of one variable by another within the context \(\Gamma\). Let \(v_1\) and \(v_2\) be any distinct variables, and let \(\Gamma\) be any formula having free occurrences of at least \(v_1\). (\(\Gamma\) may also have free occurrences of \(v_1\) and other variables as well.) The following, along with the first law of identity: \(\sim (x)(x = x)\) (reflexivity), suffices to axiomatize identity theory.

\[
\text{ID2*} \quad (v_2)[(3v_1)((v_1 = v_2) \supset \Gamma)]
\]

I call ID2* the "why not take all of me" principle.

It has been my experience that even systems that proclaim their defiance of ID2 tend to satisfy ID2*. Unless \(\sim = \) is made manifestly deviant, it is not easy to design a semantics that counts ID2* as well-formed and does not satisfy it. The recursive definition of truth would have to keep track not merely of the value of a variable, not merely of the typographical identity of a variable, but of the quantifier, long since passed over in the recursion, which originally governed the variable. I don't say it couldn't be done, but it's hard. And, practically speaking, unheard of.

If ID2 is derivable from reflexivity and ID2*, what does it mean for a system to defy ID2 but satisfy reflexivity and ID2**? It means that something entirely independent of identity has gone wrong in the sentential or quantificational part of the system.\textsuperscript{120} Wantonness with identity has its roots in baser sins.

ID2* is also usefully applied backwards to test whether an identity sign signs identity. I wonder whether Carnap, who was already cautious enough not to use the normal identity sign, would have been quicker to concede Quine's point about his 'neutral variables' (see footnote 18) had he applied the ID2* test.

Appendix E: SCHEMATIC VALIDITY AND MODAL LOGIC

I have argued that there are (at least) two distinct notions of necessity: logical necessity and metaphysical necessity, the first benign, the second invidious.\textsuperscript{121} I concluded therefore that there are (at least) two modal logics: the logic of \(\mathcal{L}\) and the logic of \(\mathcal{M}\). But the situation is complicated by the fact that there are two notions of what a logic should attempt to capture.

Consider the sentence:

\[ (x) \sim (x \text{ is a spy} , \sim x \text{ is a spy}) \]

with the variables understood to range over persons. We call this sentence logically valid. Do we call it logically valid because it would be true no matter what the non-logical facts were (i.e., no matter what persons there were and no matter what of them were spies)? If so, we have in mind what I, with some hesitation, call modal validity. (Set theoretically represented by the technical notion of truth in every model.) Do we call the sentence logically valid because, given the facts as they are, it would be true no matter how we were to reinterpret its non-logical signs (i.e., no matter what grammatically appropriate expressions are substituted for the non-logical signs and no matter what domain of discourse the variable is taken to range over)? If so, we have in mind what I unhesitatingly call schematic validity. The notions are different, but for classical first order extensional logic they pick out the same validities. This is a wonder, and wonderful.\textsuperscript{122}

I will not duplicate Quine's excellent technical discussion of the classical case.\textsuperscript{123} What is important for our purposes is that the two notions do not pick out the same class of validities for the logic of \(\sim [\mathcal{M}]\). It is the modal validities of \(\mathcal{L}\) that we earlier called the logic of logical necessity. But although \(\sim [\mathcal{L}]\) Orcutt is a spy is a valid, it has the counterinstance (i.e., false reinterpretation): \(\sim [\mathcal{L}] (\text{Orcutt = Orcutt})\). Hence, it is not schematically valid.

The two approaches to validity interact with the two notions of necessity in a somewhat surprising way that makes it difficult to determine whether certain modal logicians are studying logical necessity or metaphysical necessity. For the sentential modal logic \(S_5\), the theorems can be regarded either as the modally valid laws governing \(\mathcal{M}\) or as the schematically valid laws governing \(\mathcal{L}\). The laws are the same.\textsuperscript{124} When quantification is added, the laws are still
largely the same. Whatever is modally valid for $M$ is still schematically valid for $L$. But there are schematic validities for $L$ (for example, $
eg L \vdash (3x)(3y) (x \neq y)$) that are not modal validities for $M$.

Carnap and C.I. Lewis seem rather clearly to have $L$ in mind as their modality.\footnote{This is an endnote.} Whereas Kripke, and perhaps Church, seem to have $M$ in mind.\footnote{This is another endnote.} I have sometimes wondered whether the self-righteous rejection of the essentialism charge by certain modal logicians (despite their leaving various negative $L$ validities undecided) did not stem from the unarticulated thought that schematic validity was their project.

NOTES

3. I note that in reprinting the paper, the editor of *The Ways of Paradox* has acquitened Quine of premeditation.

4. This move—to express the verb as what Russell called a propositional attitude—is an important one. Russell’s term reflects his semantical view that the objects of the attitudes are ‘propositions’. Our use is only to indicate a syntactical feature of the verb phrase. The move is not without difficulties. See Appendix A: Paraphrasing into Propositional Attitudes.

5. There is a subtle difficulty here that is obscured by the first person formulation. Although “I want a sloop” may be revised as “I wish that I have a sloop”, it is incorrect to rephrase “Ernest wants a sloop” as “Ernest wishes that Ernest has a sloop”. Ernest may not know that he is Ernest, and thus his benevolent wish that Ernest has a sloop may be irrelevant to his own wanting a sloop. We must somehow capture the idea that what Ernest wishes has the first person form “I have a sloop”. What is required is a version of Castañeda’s “Ernest wishes that he-himself has a sloop” (H.N. Castañeda, “Indicators and Quasi-indicators”, *American Philosophical Quarterly* 4 (1967) or a variation on the formulations of belief $de se$ by Lewis or by Richard [D. Lewis, “Attitudes De Dicto and De Se”, *Philosophical Review* 88 (1979), Mark Richard, “Direct Reference and Ascriptions of Belief”, *Journal of Philosophical Logic* 12 (1983)].

6. When I echo Quine’s words, sometimes I quote, sometimes I don’t.

7. I properly should say that in 1956 Quine did not doubt, since 21 years later in “Intensions Revisited” [in P. French et al. (eds.), *Midwest Studies in Philosophy II* (University of Minnesota Press, 1977); reprinted in Quine’s *Things and Theories* (Harvard, 1981)] he champions a more severe epistemological stance and renounces this position. His renunciation has the strange and seemingly unnoticed consequence that his own ultimate formulation ((27) of Q&PA) of the notional sense of “Someone wants a sloop”:

$$\exists x (x \text{ wishes that: } \exists y (y \text{ is a sloop } \land x \text{ has } y))$$

also ceases to make sense.

8. Page 142 in “Reference and Modality”, *From a Logical Point of View* (Harvard, 1953); the paper is somewhat revised in the second edition, 1961.

9. One obvious reason would be that in their usual formulations the logical inference rules of universal instantiation and existential generalization fail. But that is not Quine’s reason. Already in “Notes on Existence and Necessity” [Journal of Philosophy 40 (1943); reprinted in L. Linsky (ed.) *Semantics and the Philosophy of Language* (University of Illinois Press, 1952)] and again in “Reference and Modality”, Quine anticipates one version of what is now called “free logic” by remarking that these inference rules are “anomalous as an adjunct” to the purely logical theory of quantification. See, for example, “Notes on Existence and Necessity”, paragraph 9 of section 2, refined in “Reference and Modality”, paragraph 4 of section 2. Also, see Church’s comments on this matter in his review of “Notes on Existence and Necessity” [Journal of Symbolic Logic VIII: 45].

10. There is much of interest in the relation between the two syntactical forms independently of the use Quine makes of them. See Appendix B: The Syntactically De Re.

11. The original purpose of reforming (2) into the propositional attitude form (3) was to exhibit the two readings of “I want a sloop” as a grammatical ambiguity. The analysis in terms of a lexical ambiguity makes this goal unachievable. There remains no obvious reason not to leave (2) unregenerate. Quine seems not to have considered this course, which is considered at the end of Appendix A.

12. See, for example, the third to last paragraph of his reply “To Kaplan” [in D. Davidson and J. Hintikka (eds.), *Words and Objects* (D. Reidel, 1969)].

13. Although Quine is not explicit about it, this argument is almost surely aimed at the intensional logic of *Principia Mathematica* in which expressions like “the proposition that $x$ is bald” are said to signify propositional functions and to be accessible to quantification. More about this later on.

14. Nathan Salmon pointed out the possibility that the occurrence be within quotation marks and suggested the use of “bindable” to forestall this possibility.

15. The interested reader can easily find the citations which verify Quine’s commitment to each of steps 1–4. It may be objected that although the argument is one whose premises Quine probably believed and which he might have given, there is no direct evidence in any of the papers from 1943 on that he ever actually did give exactly this argument. I agree. Had he filled in the details of steps 5 through 8 he would have immediately seen the fallacy in 4. But Quine clearly believes himself to have given an argument in establishing conclusion (iii) of Notes on E&N, and I still find this the best detailed reconstruction of that argument. I have already called it “speculation”.

16. Although it is not necessarily the occurrence to be supplanted, as is claimed in paragraph 2 of R&M: “Failure of substitutivity reveals merely that the occurrence to be supplanted is not purely referential . . .”. Note also that I have shifted from the “purely designative” language of Notes on E&N to the “purely referential” language of R&M.

17. R&M, last half of paragraph 8.

18. Ibid., paragraphs 8 and 9 of section 2.

19. The thoughtful exponent also speculated that perhaps it was Quine’s 1943 use of “designate” rather than “refer” that led him to assume tacitly that the semantics was determined by the position rather than the occupant. “Designation”, he said, brings only closed terms to mind; variables don’t “designate”, they refer.

20. Such at least seems to be the Fregean tradition. There is little that I have been able to find in Frege’s writings that goes directly to this point although his examples all
suggest that it is the context which determines whether the constituents have direct or indirect denotation. He does not explicitly discuss the question of a variable—which presumably has no indirect denotation—occurring in such a context, though he does indicate, in the letter to Russell quoted below, that he is flabbergasted by Russell’s idea that the proposition expressed by a sentence might have an object as one of its components.

Frege, of course, gives the matter an added twist. By using his notion of indirect denotation, he restores the occurrences of singular terms to purely designative status, though with an altered designation. Thus he validates quantification into such positions provided that the values of the variables are of the kind indirectly denoted by the singular terms. Church follows Frege in this.

An alternative, adopted by Carnap, is to accept the Fregean injunction against variability in position without using a notion of indirect denotation, and thus to be driven by Quine’s argument to the conclusion that quantification in must receive a non-standard interpretation. Carnap uses what he calls “neutral variables” with both “value-extensions” and “value-intentions”. He appears to acknowledge Quine’s criticism that this usage is non-standard but argues that the deviance is benign. See especially section 44 of Meaning and Necessity (University of Chicago Press, 1947; enlarged edition, 1956) and footnote 11, page 892, of The Philosophy of Rudolf Carnap edited by P. A. Schilpp (Open Court, 1963).

21. Church’s formalization appeared in abstract in 1946 and full-blown in 1951 “A Formulation of the Logic of Sense and Denotation” [in P. Henle et al. (eds.), Structure Method and Meaning (Liberal Arts Press, 1951)]. His “Outline of a Revised Formulation of the Logic of Sense and Denotation” appears (in two parts) in Nous 7 (1973): 24–33 and Nous 8 (1974): 135–156, wherein see further references. Within Church’s rather complex system it is, in fact, possible for an occurrence of an individual variable within the scope of a modal operator to be bound by an initially placed quantifier. Therefore a somewhat more sophisticated formulation of Quine’s proscription is required in order to show that Church’s system conforms to it. But it does. The critical point is that despite the multitude of syntactical forms, Church’s version of quantified modal logic, like Carnap’s in Meaning and Necessity, does not permit expression of the characteristic statement of the familiar version—that an individual, independently of how it is conceptualized, has some property necessarily.

Quine should recognize and applaud the fact that Church and Carnap share his intuition that it is only an individual-under-a-concept that can be said to have a property necessarily. Church is careful to point out that even the statement that an individual has only contingent existence must be “corrected in form in accordance with a Fregean analysis.” We can say, regarding various concepts of an individual, that they are possibly vacuous, but it would not be meaningful to say of the individual itself that it might not have existed “[Outline of a Revised . . . ” 147, 148].

As an historical sidelight I note that the characteristic statement is expressible in the system of Carnap’s path-breaking “Modalities and Quantification” [Journal of Symbolic Logic 11 (June, 1946)], which preceded Meaning and Necessity.

24. A further result of Quine’s unwillingness to make use of indirect denotation is this. Quine claims the identification of his notions with Frege’s on the basis of a common criterion: substitutivity of identity. But I think that Frege regards failure of substitutivity more as a consequence of an indirect ‘occurrence’—that is, as a consequence of the fact that the occurrence manifests (to Frege) has indirect denotation—than as a criterion for it. Were substitutivity to fail in a case in which no entity plausibly presented itself as the object of indirect denotation, I think Frege would not call the occurrence “oblique”. ‘Accidental’ occurrences like that of the term “cat” in the context “cattle” may be of this kind.

26. Thus, there is no threat of logical inconsistency from quantification into an indifferentially notated, nor, as has been suggested, is there an immanent logical threat of modal collapse. See, for example, pp. 197–198 of Word and Object (The Technology Press of M.I.T., 1960). D. Føllesdal ["Quine on Modality", in Words and Objects] sees this threat as among Quine’s primary challenges to modal logic. However, if worse comes to worst, we can always fall back on the logician’s trick.

27. The interdefinability claim, however, seems too strong, and stronger than needed for mere re-ambiguation. Especially in the case of belief, the bilateral definition seems incorrect and doesn’t square with intuitions of Q&PA. See Appendix B.

28. In such expositions, Quine provisionally adopts a strategy like that of Frege, assigning an indirect denotation to explain failure of substitutivity. Even Quine’s choices of indirect values: intensions and expressions, mirror Frege’s.

29. Intensional entities are those of a kind capable of being the intension of an expression, thus propositions, properties, etc. I use “intension” (of an expression) in a loose but traditional way to contrast with “extension” (Tradition speaks more precisely of extension than of intension.) My use of “intension” commotes neither Carnap’s technical use (according to which logically equivalent expressions have the same “intension”) nor a use designed specifically for the propositional attitudes.

30. In 1903 Russell claimed that the points of disagreement between Frege’s theory and his own were “very few and slight”. [The Principles of Mathematics (George Allen & Unwin, 1903), pages 501–502.] But two years later, “‘On Denoting’ includes a lengthy argument purporting ‘to prove that the whole distinction of meaning and denotation has been correctly conceived. . . . Thus the point of view [to which this distinction belongs] must be abandoned.” [Mind 14 (1905): reprinted in Contemporary Readings in Logical Theory and in many other places.] The unintelligibility of the argument supporting this claim has caused many to ignore its secessionist implications.

Quine tells us that his metaphor of opacity (roughly, Frege’s oblique de-ontologized) is intended to contrast with Russell’s use of transparency. The contrast in notions chosen for highlighting reflects an important difference in paradigms between Frege–Quine and Russell. Whereas Frege–Quine regard opaque contexts as deviant and what Russell called transparent contexts as the norm, Russell regards transparent contexts as deviant and opaque contexts as the norm. As one pursues these differences one comes to see why Russell did not regard descriptions as ‘denoting’. Their normal semantic value for Russell is closer to Frege’s sense than to Frege’s denotation. This point must be kept in mind when reading the work of contemporaryRussians like R. Marcus’ “Modalities and Intensional Languages” [Synthese 13 (1961); reprinted in Contemporary Readings in Logical Theory and elsewhere].

In connection with what is ‘normal’, I should note explicitly that I do not understand Quine’s claim that the elimination of singular terms other than variables does not make opacity less problematic. It seems normal to regard descriptions as Frege did, as denoting, and thus to find failure of substitutivity to be prima facie puzzling. But who, other than Frege and his followers, ever thought that it was normal (gewöhnlich) to regard
predicative expressions as standing for their extensions. As we all know, extensional contexts are simpler, but are they the norm? (Can you remember how odd it seemed that all those sentential connectives were truth functional?) I'm with Russell on this one. I don't see failure of predicate extensionality as prima facie puzzling.

31. This was the view of Principles of Mathematics. In the later, better known, "On Denoting" stage of Russell's views the properties in these complexes were no longer held together in subject position but were distributed throughout the proposition. The only explicitly subject-predicate propositions remaining were the singular propositions.

32. The thesis is argued in my "How to Russell a Frege-Church" Journal of Philosophy 72 (1975); reprinted in M. Loux (ed.), The Possible and the Actual (Cornell, 1999). Therein I cited two ways of formulating a view I called "Hacceitism", the first in terms of possible worlds, the second in terms of singular propositions. As will emerge below, I now regard the second formulation (or a descendant of it) as having wider applicability and being more closely connected to our understanding of opacity, as well as being more ontologically congenial.

33. The correspondence is translated in G. Gabriel et al. (eds.), Gottlob Frege: Philosophical and Mathematical Correspondence (Basil Blackwell, 1980). See especially pages 159, 163, 169. I have used the original "Bedeutung" where the translator wrote "meaning". I wish to thank Joseph Almog for bringing these apt quotations to my attention.

34. Frege's incredulity surely stems from the point that for an 'object of thought' to be an object of thought, all of its parts have to be thinkable. According to Frege, material objects are not, in this sense, thinkable. They are presented to us only indirectly, being represented by some concept. It is these representations that are to be the parts of an object of thought. There is an asymmetry in intelligibility here; one which I have observed in myself and others. From Russell's point of view, Frege's theory looks rather like a subtheory of his own in which the singular propositions are excluded, and thus proper names that do not abbreviate descriptions are excluded. From Frege's point of view, Russell's way of 'extending' his (Frege's) ideas is utterly baffling because it seems to miss the point (as well as the method) of the whole enterprise.

35. Quine is aware that the Conservation of Intensionality governs the analysis of psychological verbs. The move (be it retreat or advance) to replace intentional entities with linguistic ones shifts the intensionality from the objects to its relations, from variables to types, to what he calls ideological. This shift is one that Quine has ever been happy to make. An interesting earlier discussion of these matters was set from what Quine calls ideology.

36. The result of surrounding an expression with arc quotes is here taken to abbreviate the expression formed by: quoting the contained expression, followed (for the alphabetically first variable α free in the contained expression) by ,α as value of , followed by α in quotes, followed (in alphabetical order for all other variables β which occur free in the contained expression) by ,β as value of , followed by β in quotes.

37. We close formulas, resulting in a closed formula. We valuate formulas, resulting in a valuated formula. Both are kinds of sentences. A sentence achieved entirely by closure is a closed sentence; one achieved partially by valuation is a valuated sentence.

38. It is easy to represent both kinds of valuated expressions, if traditional expres-
This would be to regard quotation names as not really forming contexts at all. Alternatively, if we regard quotation marks as a non-extensional functor, and the occurrence of "x" as part of the argument expression to the functor, we might say that free occurrences of variables within the argument expression are no longer free after application of the functor. (I hesitate to say that the quotes 'bind' the free occurrences of variables.) Nathan Salmon has urged that both conceptualizations be taken seriously.

50. Why then, you ask suspiciously, denonimize at all? In part for the reasons of the preceding section; in part to explore a model of a 'quotation context' along the lines of the second alternative of the preceding footnote; in part for future use; in part for fun.

51. Possible doubt is raised in the autobiographical footnote to Appendix C.

52. Raised in Q&PA, discussed in "Reply to Kaplan".

53. I cannot resist pointing out that if indexicals appear in the direct discourse, we cannot be too literal. "Ralph Says-quote I am a spy" does not imply "Ralph says that I am a spy". (Do not allow reactionary sentiments to make you uncomfortable with the naked "I" in the Says-quote context. Remember the phantom quotes.)

54. It is an oddity that "Says-quote (φ and ψ)" implies "Says-quote φ" and "Says-quote ψ". The converse, of course, fails.

55. It is what we may call the direct discourse, or literal, epistemic notions that are subject to this liability, like the notion of belief according to which to believe φ is, roughly, to be disposed to assent to φ. (As we have seen, the direct discourse structure of the intuitive notions does not prevent its being brought into operator form.) We can construct indirect discourse versions of belief that allow any degree of latitude in our reports, thus building in closure conditions.

56. Consider an arbitrary operator O and the sentence:

(P) \( \exists x O(x = \alpha) \)

where \( \alpha \) is not a variable. Does (P) confer the special privilege of acting as an instantiaal term upon \( \alpha \) (as Quine claims in "Intensions Revisited", page 120)? (P) is true in a model just in case a valuation of \( (x = \alpha) \) is in the extension of O in that model.

Now suppose \( x = \alpha \) is in the extension of O. What requires any valuation of "x is a spy" to be in the extension? Nothing, unless the extension were closed under a certain form of logical consequence, but it need not be. Thus (P) alone does not imply that a certain can serve as instantiaal term for application of quantifier rules.

57. More strictly, they added good old first order logic to modal logic. They did not, like Carnap, Church, and others, rethink the nature of quantification theory as it interacts with modality. See R.C. Barcan and R.B. Marcus, "A Functional Calculus of First Order Based on Strict Implication", Journal of Symbolic Logic 11 (1946).

59. There is a way other than by 'substitutivity' to derive Marcus's law from Marcus's law from "(x) \( \exists y (x = y) \)". See Appendix D: The Second Law of Identity.

60. A speculation: it may be that what distinguishes logical truth from the invidious forms of necessary truth simply the fungibility of individuals.

61. "Modalities and Intensional Languages".

63. The same result is obtained if the method of proxy names is used, the names are Quinized into descriptions, the descriptions are Russellled away, and the existence condition is dropped for the reason stated above.

64. An argument of Quine may be regarded as pressing this point in the opposite direction. If we were to regard arbitrary uniquely specifying predicates as proxies, there would be a 'modal collapse' of necessity into truth. See, for example, Word and Object, page 198.

65. See, for example, page 155 second edition of From A Logical Point of View, and elsewhere.

66. Word and Object, page 199.

67. I have purposely chosen a formulation that avoids complex singular terms such as "Quine" in favor of predicates and quantifiers. I could have avoided even "Quine" if he is right.

77. Another alternative, not ruled out by modest methods, is that singleton Quine would be empty, while our null set would have singleton Quine (an empty set) as its only member. This seems bizarre.

78. For references to further reasoning about these matters and for an enlightening...
discussion, see the long footnote 10 on page 89 of N. Salmon’s Reference and Essence (Princeton University Press, 1981). The point of the footnote, like the overall point of this valuable book, is that I.A.E. is not derivable, as some may have thought, from generally accepted non-essentialist premisses. On this, Quine, Salmon, and I stand together.

79. Recall that it is just uniterated necessity that is at issue. A Sentence of the language of first order logic is a consequence of a set of Sentences if it is true in every model they are.

80. For further reflections on the relation between M and L see Appendix E: Schematic Validity and Modal Logic.

82. Found with the help of Dagfinn Føllesdal. I note that the argument does not appear in the approximately coeval first edition of From A Logical Point of View.

83. Terence Parsons, in his elegant little paper “Essentialism and Quantified Modal Logic” [Philosophical Review 78 (1969); reprinted in L. Linsky’s Reference and Modality] follows the methodology of Quine and Marcus (“Essentialism in Modal Logic”, Nous 1 (1967)) but gives a different syntactical characterization of the ‘form’ of I.A.E. Parsons starts from a paradigm like:

\[(\exists x) \Box x \text{ is rational} \cdot (\forall x) \text{ is rational}

and generalizes it, in a subtle way, to account for other than monadic formulas. His result is opposite to Quine’s. Using what amounts to logical necessity—but under the description “maximal Kripke model”—he shows that no sentence of the invidious form is a theorem or even true at any ‘world’ of the model. The paper also contains interesting remarks regarding I.A.E. in modalized number theory.

84. Parsons and Marcus must also have this idea in the back of their minds, for whenever they came up with a syntactical characterization of invidious essentialism that was satisfied by what I call ‘logical necessity’, they rejected it as too weak.

85. Unless we could make out a case that, like the distinction between individuals that are identical and those that are not, the seemingly invidious distinctions were logical distinctions.

86. Word and Object, pp. 198–199.

87. Knowledge and Belief (Cornell, 1962).

88. Of course, the fact that there is no methodological requirement to use surrogates does not mean that their use is always inappropriate. In the case of the propositional attitudes, in contrast to the case of modality, it would not be unnatural to expect the classification of valued sentences to be dependent on a prior classification of the closed sentences, and it would not be unnatural to think of this dependence in terms of surrogates. At least I did not think it unnatural when I proceeded this way in “Quantifying In”. I now have some doubts.

89. What we count as part of context will affect what linguistic forms are contextually determinate (as will the way in which we individuate ‘meanings’). But one can imagine cases in which even a wide notion of context does not fix the ‘meaning’ narrowly enough for the relativized notion of truth. Vague terms may be of this sort.

90. Quine does seem to acknowledge that relativity to context need not unfit a language for completely precise use when he tells us how ‘eternal’ expressions are introduced on the basis of demonstratives. See for example section 21 of Word and Object.

91. In The Ways of Paradox.

93. I have two highly amorphous worries regarding Quine’s conception of scientific language. My first worry is that he too much divorces the resources appropriate to the pronouncement of scientific results (eternal sentences) from the resources required to do science collaboratively in the laboratory. I emphasize “required” rather than “used”, because Quine sometimes writes as if the language of the laboratory (with all its fugitive features: tense, demonstratives, indexicals, perceptual reports, vagueness, etc.) has only practical advantages over the ‘eternal’ language of the lectern. My second, and related, worry is that the conceptual and linguistic resources of indexicals may be essential to us because of our subjective perspective on the world (roughly, the way perceptual information flows in and action flows out). Our subjective perspective requires special, non-eternal, resources for internal processing. It is a perspective which science can study but cannot, and should not, take. For relevant views I largely share, see T. Burgin, “Belief De Re”, Journal of Philosophy 74 (1977), and J. Perry’s “The Problem of the Essential Indexical”, Nous 13 (1979).

94. There is a question, in purported cases of implicit contextuality, whether what is at issue is truth or conversational propriety. Quine would probably reject this dichotomy in the critical cases.

95. “Reply to Professor Marcus”.

96. The new technology is not yet fully developed and is untested in the marketplace, but let us assume it pans out.

97. Again, much more detail is required to solidify the two pictures and to make plausible the links to current theories.

98. Joseph Almog even wonders whether logical necessity, as I characterize it, should be considered a modality at all, or should it be thought of merely as a matter of ‘combinatorics’.

99. Explicit, stipulative surrogatism could make it appear that one had been forced out of the hard line. But it could also make it appear that one had been forced into it.

100. It should be noted that the Fregan analysis of intensional verbs, as developed by Church, does not require this transformation. See section I of “How to Russell a Fregian Church”.

101. Alonzo Church, “The Need for Abstract Entities in Semantic Analysis”, in Proceedings of the American Academy of Arts and Sciences 80 (1951): footnote 14. Church’s examples are: “I am thinking of Pegasus”, “Ponce de Leon searched for the fountain of youth”, and “Barbara Villiers was less chaste than Diana”.

103. Or, in a less common sense of “fear”, to reverse them.

104. There are the makings here of an ad hominem against Quine’s rejection of relational attitudes. First we provoke him to seek something notionally. (“Quick, get a policeman, any policeman” we shout.) Though he may have no relational attitudes, his own analysis (with our amendment) requires that he strive to have one. How long will he be able to maintain this ambivalent state of rejection mingled with desire. (I predict that he will soon be driven to utter contextuality.)

106. By treating only sentence-forming sentential operators, I swallow up the sub-
ject (e.g. "Ralph") of a propositional attitude verb (e.g. "believes that") into the verb (e.g. "Ralph-believes-that"). It is natural to want to break-out the subject, perhaps for quantification, and this is easily done. Nothing of theoretical importance would change, though the description of the syntax would be more tedious.

107. The only compound predicate expressions I permit are those formed by syntactically de re operators. Quine takes a different approach to the syntax of the syntactically de re, introducing compound predicate expressions in their own right, in a way that suggesting they might well appear within the operand of the syntactically de dicto. If so, Quine’s syntax provides more expressive power to the syntactically de dicto, and thereby affects some of the metalogical issues discussed below, in particular, those involving the "translation" of the syntactically de re back into the syntactically de dicto. D. Wiggins and C. Peacocke both follow Quine’s syntax in their treatment of the syntactically de re. ["The De Re ‘Must’: A Note on the Logical Form of Essentialist Claims” and “An Appendix to David Wiggins “Note”,” both in G. Evans and J. McDowell (eds.) Truth and Meaning (Oxford, 1976)]. I do not think my syntax superior to Quine’s, but it is simpler and steers clear of some intriguing issues that are best held in abeyance for now.

Note that I italicize the variable binding de re operators. I would use negation as an example if I could figure out how to italicize a tilde.

108. Quine appears to share this view. In Q&PA, Quine denies: \[
\{\text{Bel} \,(x) \ (x \text{ is a spy} \quad \neg \text{is a spy}) \} \]
(see (23) of Q&PA), while affirming what is virtually:
\[
\{\text{Bel} \,(x) \,(x \text{ is a spy} \quad \neg \text{is a spy}) \} \]
Oricutt

What Quine actually affirms (in (15) and (22) of Q&PA) is equivalent to:
(i)
\[
\{\{\text{Bel} \,(y) \ y \text{ is a spy}\} \quad \{\text{Bel} \,(y) \ \neg \text{is a spy}\}\} \]
Because Ralph might fail to ‘put two and two together’ (i.e. to believe the conjunction of whatever he believes separately), we cannot immediately conclude:
\[
\{\text{Bel} \,(x) \ (x \text{ is a spy} \quad \neg \text{is a spy}) \}
\]
xx
But I think Quine would not object to counting it as true. We could easily modify the story to make it as plausible as (i).

109. I believe that we can capture the form of closure that we would attribute to Bel if Ralph were logically omniscient by using the methods of section XIV.

110. I assume that Bel dominates over conjunction. Then (28) yields \[(\exists x)(x = \text{the Mayor} \supset \text{Bel} \,(x \text{ is a spy}))\] and \[(\exists x) \text{Bel} \,(x = \text{the Mayor})\]. Hence if the latter sufficed to make “the Mayor” an instantial term, the former would yield (29). This result is not dependent on the use of belief rather than knowledge. The story could easily be amplified in a way that would justify a knowledge claim in (28). Still (29) would not follow.

111. Even putting aside the special delicacies introduced by iteration of propositional attitudes.

112. An analogous difficulty appears if the translation is attempted using universal quantifiers.

113. I speak intuitively. For the matter to be a well defined logical problem would require model theoretic or axiomatic formulations of the two forms of a particular operator.

114. These matters arose in connection with footnote 5.

115. The operator "Bel" might also be taken to form an n-1 place predicate, omitting the redundant argument expression “Ralph”. I prefer it as it is.

116. In Q&PA Quine doesn’t say how, in general, to translate quantified de dicto forms into the de re form. In “Intensions Revisited” the specific form of a bilateral interpretation between the syntactically de dicto and the syntactically de re is proposed, first for necessity and then for belief. There Quine omits to articulate.

117. The idea of arc-quotes stems from my analysis in “Quantifying In” of Quine’s corners.

118. Autobiographical note: When I first set out to try to construct a non-Fregean semantics in “‘Dhat” [in P. Cole (ed.), Pragmatics: Syntax and Semantics 9 (Academic Press, 1978); reprinted in Contemporary Perspectives in the Philosophy of Language, written during the summer of 1970] I worked from the idea that the use of a demonstrative could be thought of as a device for putting an object into the very syntax of the sentence, as if we were to display the object and then utter a predicate, like the caption “wants to party” worn on a T-shirt. From this point of view, a closed sentence containing a demonstrative is, as it were, syntactically incomplete. “The mere wording, as it is given in writing, is not a complete expression. . . . It must be supplemented by certain accompanying conditions of utterance . . . . The pointing of fingers, hand movements, glances may belong here too.” (Who said that in 1918?) Thus a use of a closed sentence containing a demonstrative becomes a token of a valuated sentence. (I here contrast a use with an arbitrary token such as this one: It is blue.) When the linguistic tokens are not sounds, but material objects: piles of ink or twisted neon tubes, it seems easy to set another material object among them. There remains the singular result that the object is a token of itself.

119. It has long been my view that this ‘ambiguity’, when translated back into the intentional framework of singular and general propositions, is one of the keys to understanding Russell’s lengthy ‘unintelligible’ argument against Frege’s “On Denoting”, an argument which I see as prefiguring Carnap’s worries about oblique senses. But that’s a story that also requires a lengthy argument.

120. It was Saul Kripke who first pointed out that one of the wanton systems failed to satisfy a quantifier law. See footnote 13 of Naming and Necessity. D. Lewis does not agree. See his Philosophical Papers, Vol. 1 (Oxford, 1983), pp. 45–46.

121. I have taken the easy way by treating logical necessity as preordained by classical logic. A more probing, less prejudiced, investigation of logical necessity, of what is the domain of logic proper, would blur the dividing line between logical and metaphysical necessity.

122. There is, of course, a third equivalent notion, the notion of derivational validity, based on the idea of a truth preserving syntactical transformation.

123. See Chapter 4 of Philosophy of Logic (Prentice Hall, 1970). I should note, however, that although he professes tolerance, “The theorems establishing equivalence among very unlike formulations of a notion—logical truth or whatever—are of course the important part. Which of the formulations we choose as the somehow official definition is less important. . . . he stacks the deck in two ways: by taking as his official explicandum, ‘a sentence is logically true if all sentences are true that share its logical structure’, and by introducing what I call modal validity directly by a set theoretical representation, with no mention of the idea that the sets could be thought of as representing possible extensions of the predicates.

124. This result was first obtained by Steven K. Thomason [“A New Representation of SS”, Notre Dame Journal of Formal Logic XIV (1973)] based on the completeness theorem of Saul Kripke [“A Completeness Theorem in Modal Logic”, Journal of Symbolic Logic 24 (1959)].

125. Carnap develops almost exactly the modal validities of logical necessity in “Modalities and Quantification”.

126. Church doubts that it should be a principle of logic that there are true propo-
itions that are not necessary ["A Formulation of the Logic of Sense and Denotation", page 22], and his heuristic models do indeed make all true propositions necessary when there is only one 'possible world' ("Outline of a Revised Formulation of the Logic of Sense and Denotation"). This suggests to me that he has metaphysical necessity in mind, despite the fact that he calls his notion 'logical necessity'. In my understanding of Church's system both logical necessity and metaphysical necessity are used. The first to formalize the principle of individuation for senses: that expressions express the same sense if and only if they are equivalent by logical necessity. The second to capture the notion of necessity associated with the heuristic of 'possible worlds'. I should caution that if my understanding is correct, Church erred in the way he used the heuristic models to individuate senses. Hence, I have probably misunderstood him.

TABLE OF CONTENTS

I: The transition in Q&P A shows that Quine believed that there was a logical principle forbidding quantification into opacity. 229

Part A: THE ALLEGED THEOREM

II: Quine's solution in Q&P A is to find a lexical ambiguity and distinguish notional and relational senses. This reinforces the point that the problem at the transition is logical. 231

III: The argument in Notes on E&N is reconstructed and discussed. 233

IV: The views of the thoughtful exponent in Dubrovnik are given. Quine's outlook is linked to Frege's. 236

V: Not only is the proof for the alleged theorem fallacious, the alleged theorem can be shown false by re-ambiguation—a logician's trick. But does re-ambiguation give a coherent interpretation? 236

Part B: COHERENT INTERPRETATIONS

VI: We must semantically unify subject and predicate and then unify the result with the objects of notional senses. We will follow Quine's method by first invoking intensional objects and then linguistic ones. 239

VII: Russell's semantics and theory of intensional entities is developed and briefly contrasted with Frege's. Singular propositions are shown to unify subject and predicate. 239

VIII: The logician's trick won't work if the entities are linguistic. A new notational trick, arc quotation, is introduced to give the appearance of quantifying into quotation and thus to permit a kind of re-ambiguation. 241

IX: A coherent interpretation for the re-ambiguated linguistic operator is provided by introducing valued expressions, including Sentences, as the values of arc quotation names. Arc quotation is no longer a trick. 243

X: Quine's use of intensions and sentences to explain opacity needed only to be extended to singular propositions and valued sentences in order to accommodate quantification. Sentences simulate propositions. 245

XI: A methodological sermon is delivered on the hazards of nominalization. 245

XII: Direct discourse is introduced as an operator Says-quote. Quantification into direct discourse is grammatical, but one should take a hard line on its truthfulness.
